Dear Santa Claus,

*We have been good
these past decades.
Please could you
now bring us*

- *a dark matter candidate*
- *an explanation for the fermion masses*
- *an explanation of matter-antimatter asymmetry*
- *an axion, to solve the strong CP problem*
- *a solution to fine tuning the EW scale*
- *a solution to fine tuning the cosmological constant*

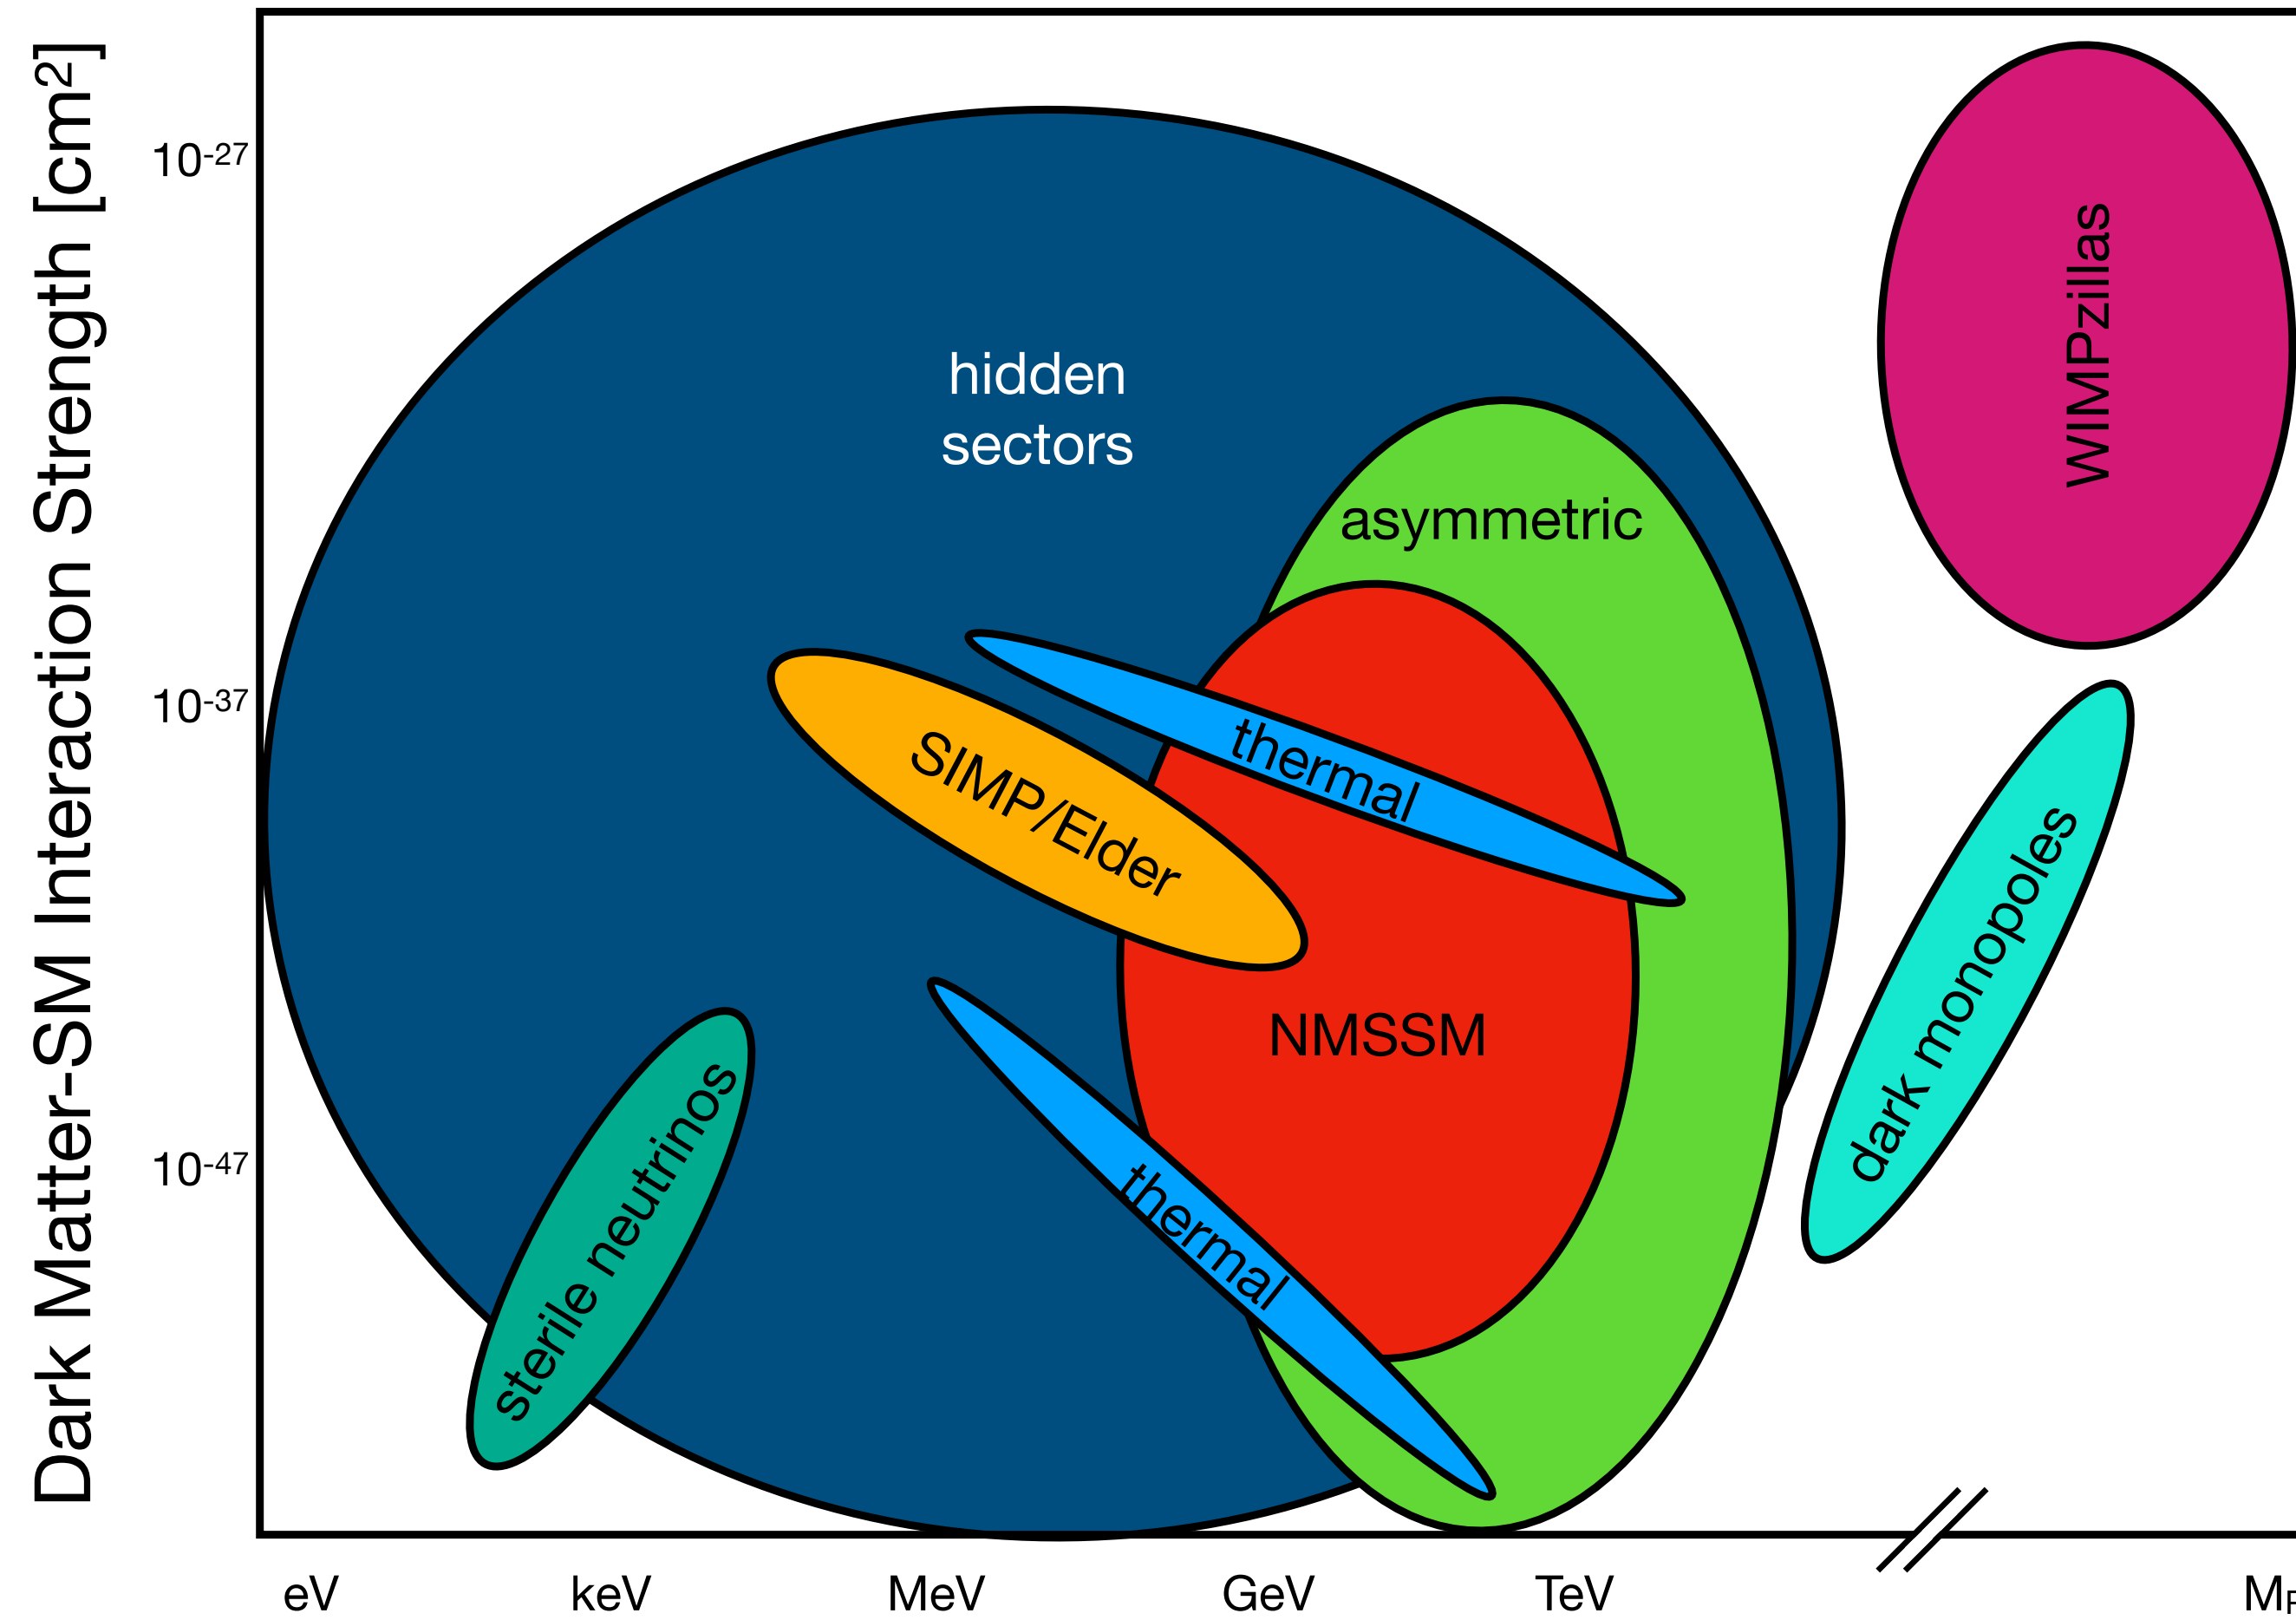

Thank you, Particle Physicists

ps: please, no anthropics

we have so far been **unlucky in
getting answers to these many
questions**

Snowmass Dark Matter report, 2209.07426

**30 orders
of magnitude
in interaction
strength**

**30 orders of
magnitude in mass**

**the standard-model particle set
is complete**

13th ICFA Seminar on

Future Perspectives in High-Energy Physics

28 November – 1 December 2023

DESY, Hamburg

the standard-model particle set
is complete

but we have been **lucky** with the
Higgs boson's 125 GeV mass

it opens a door to the most
mysterious part of the Standard
Model

desirable features of the next major HEP project(s)?

an important target to be reached ~ guaranteed discovery

exploration into the unknown by a significant factor in energy

major progress on a broad array of particle physics topics

likelihood of success, robustness (e.g. multiple experiments)

cost-effective construction & operation,
low carbon footprint, novel technologies

Higgs physics

Higgs is the last particle of the SM.

So the SM is complete, right?

The Lagrangian and Higgs interactions: two out of three qualitatively new!

$$\mathcal{L}_{\text{SM}} = \dots + |D_{\mu}\phi|^2 + \psi_i y_{ij} \psi_j \phi - V(\phi)$$

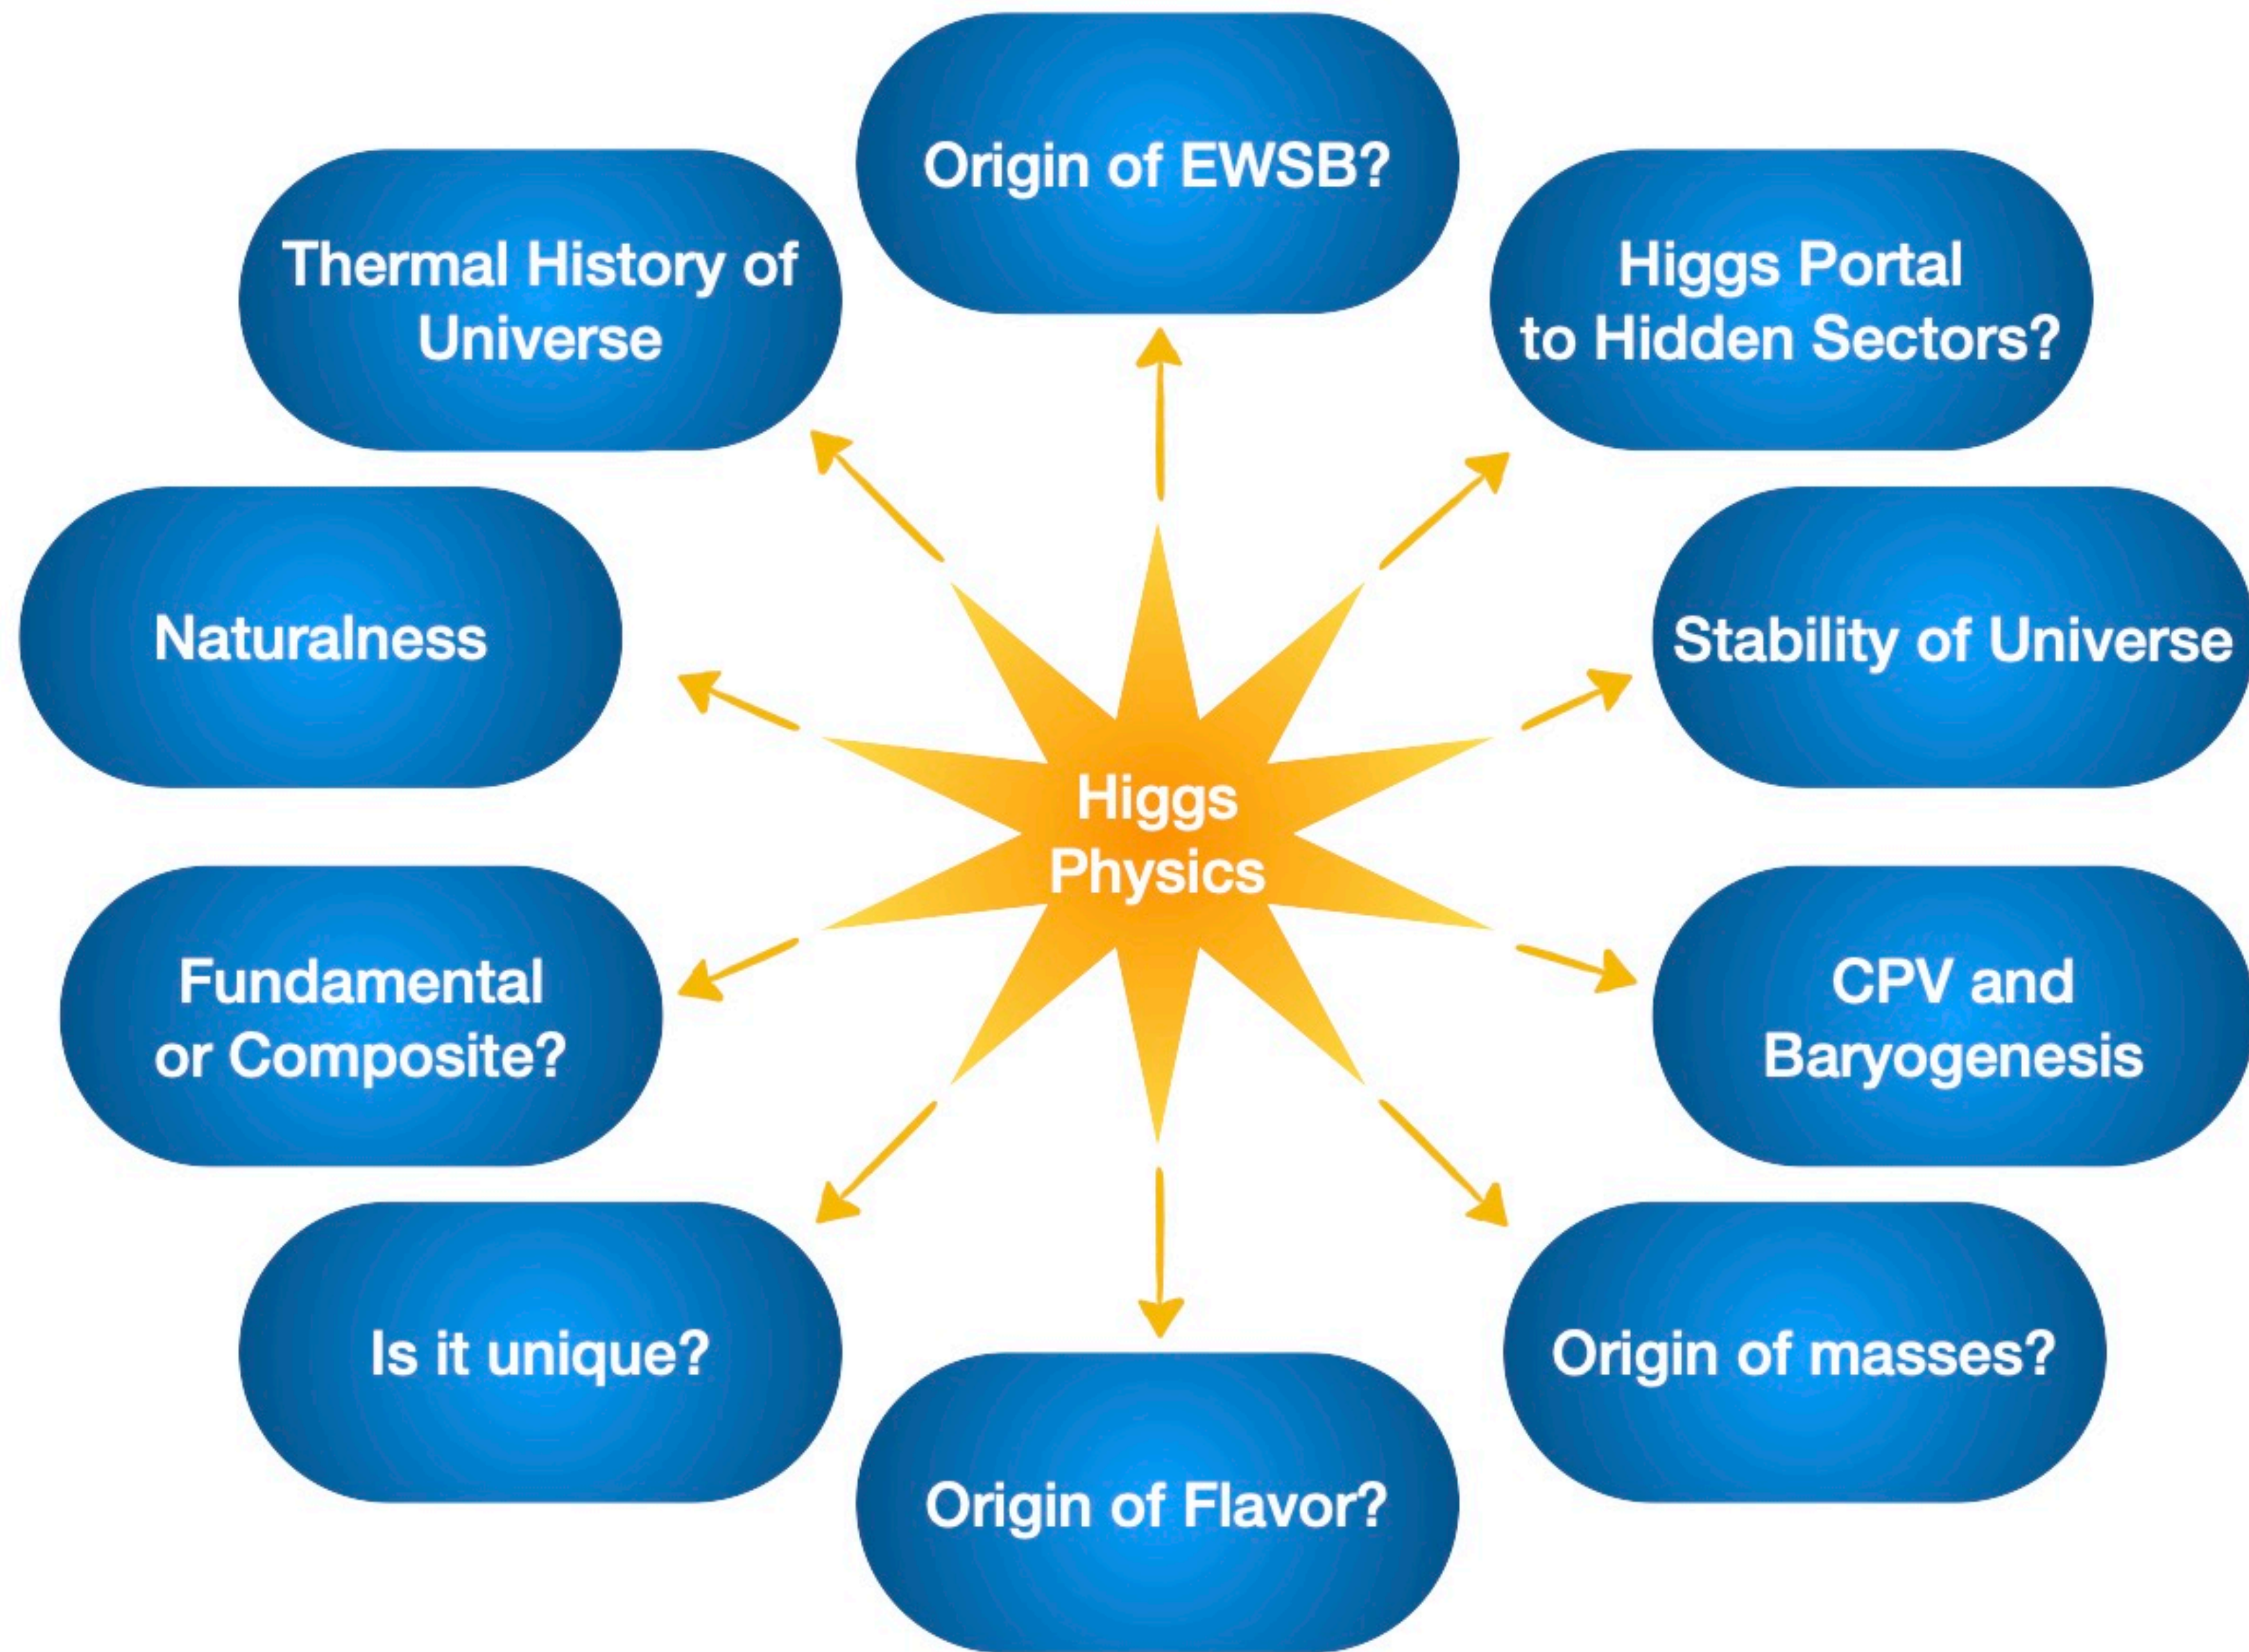

Gauge interactions, structurally like those in QED, QCD, EW, **studied for many decades** (but now with a scalar)

Yukawa interactions. Responsible for fermion masses, and induces “fifth force” between fermions. **Direct study started only in 2018!**

Higgs potential → self-interaction (“sixth?” force between scalars). Holds the SM together. **Unobserved**

Yukawa interaction hypothesis

Yukawa couplings \sim fermion mass

first fundamental interaction that we probe at the quantum level where interaction strength (y_{ij}) not quantised
(i.e. no underlying unit of conserved charge across particles)

2.2 MeV **2.2 MeV** 4.7 MeV

proton:

$\approx 938.3 \text{ MeV}$

neutron:

$\approx 939.6 \text{ MeV}$

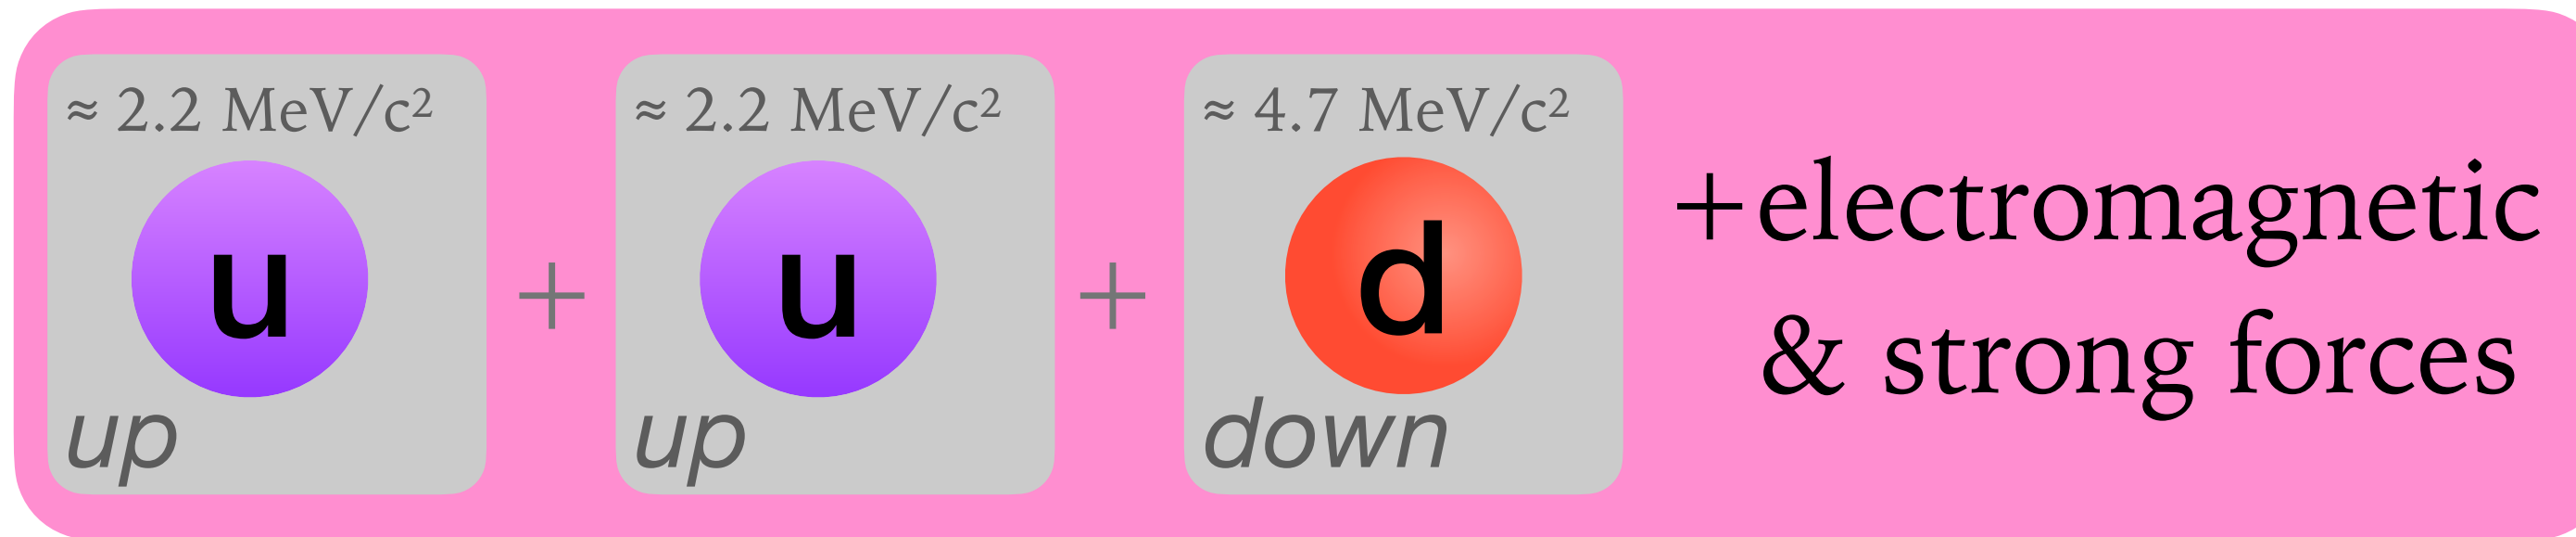

2.2 MeV **4.7 MeV** 4.7 MeV

Protons are **lighter** than neutrons \rightarrow protons are stable.

Giving us the hydrogen atom, & chemistry and biology as we know it

2.2 MeV 2.2 MeV 4.7 MeV

proton:

$\approx 938.3 \text{ MeV}$

neutron:

$\approx 939.6 \text{ MeV}$

2.2 MeV 4.7 MeV 4.7 MeV

Protons are **lighter** than neutrons \rightarrow protons are stable.
Giving us the hydrogen atom, & chemistry and biology as we know it

**Supposedly because up quarks interact more weakly
with the Higgs field than down quarks**

Why do Yukawa couplings matter?

(2) Because, within SM **conjecture**, they're what give masses to all **leptons**

$$\begin{aligned} \mathcal{L} = & -\frac{1}{4} F_{\mu\nu} F^{\mu\nu} \\ & + i\bar{\psi}\not{\partial}\psi \\ & + \boxed{Y_i y_{ij} \psi_j \phi} + h.c. \\ & + |D_\mu \phi|^2 - V(\phi) \end{aligned}$$

This equation neatly sums up our current understanding of fundamental particles and forces.

Bohr radius

$$a_0 = \frac{4\pi\epsilon_0\hbar^2}{m_e e^2} = \frac{\hbar}{m_e c \alpha} \propto \frac{1}{y_e}$$

electron mass determines size of all atoms

it sets energy levels of all chemical reactions

**currently we have no evidence that up and down quarks
and electron get their masses from Yukawa interactions
— it's in textbooks, but is it nature?**

tantalisingly close to reach of circular e^+e^- colliders?

A side comment on the near future at LHC

- particle physics normally deals with esoteric particles that have [almost] no relation with the world as we experience it
- LHC will reach 5σ sensitivity for $H \rightarrow \mu\mu$ in the coming years (if it is SM-like), offering first proof that particles other than 3rd generation also get their mass from Yukawa mechanism
- that will be a crucial step on the way from 3rd generation Yukawas to 1st
- it deserves a big event with the world's press to announce it
- an opportunity to explain the quest for understanding the origin of the mass of the fundamental particles that we are made of

Public Domain, <https://commons.wikimedia.org/w/index.php?curid=95023097>

the Higgs potential

Higgs potential

$V(\phi)$, SM

$$V = -\mu^2 |\phi|^2 + \lambda |\phi|^4 + V_0$$

the Higgs mechanism gives mass to particles because the Higgs field ϕ is non-zero

That happens because the minimum of the SM potential is at non-zero ϕ

Higgs potential

$V(\phi)$, SM

Standard Model potential

depth is $\frac{m_H^2 v^2}{8}$ ($m_H \simeq 125$ GeV, $v \simeq 246$ GeV)

a fairly innocuous sounding $(104 \text{ GeV})^4$

Higgs potential – remember: it's an energy density

$V(\phi)$, SM

universe
lives here

Standard Model
potential

Corresponds to an energy density of
 $1.5 \times 10^{10} \text{ GeV/fm}^3$
i.e. > 10 billion times nuclear density
Mass density of $2.6 \times 10^{28} \text{ kg/m}^3$

Earth at Higgs potential density

cosmological constant & fine-tuning [classically]

$$V_{min} = \left[-\mu^2 |\phi|^2 + \lambda |\phi|^4 \right]_{\phi_0} + V_0$$

cosmological constant

$$= -2.6 \times 10^{28} \text{ kg/m}^3 + V_0 = \boxed{5.96 \times 10^{-27} \text{ kg/m}^3}$$

- V_0 needs to be fine tuned for cosmological constant to have today's size (also with respect to various sources of quantum correction)
- not the only fine-tuning problem in fundamental physics,
— arguably special in that it appears already classically
- collider physics cannot tell us anything about V_0
— but it would seem negligent not to try and establish the rest of the potential

The potential expanded around the minimum

- take h as the Higgs field excitation in units of the field at minimum

$$V = \frac{m_H^2 v^2}{8} \left(-1 + 4h^2 + 4h^3 + h^4 \right)$$

the Higgs boson mass term

prediction of the strength of HHH interaction
[modifier may be called κ_λ or κ_3]

when would we claim discovery? [5 σ in each of two independent experiments is our gold standard]

- equivalent for an interaction is a bit ambiguous — but better than $\pm 20\%$ determination is probably a reasonable target
- for something of this importance, we may be wary of relying on 20% only from a combination of N experiments — a result's robustness comes from confirmation by independent experiments
- indirect v. direct:
 - all measurements are indirect (we measure hadrons and leptons...)
 - single H is good to have
 - but HH & kinematic structure brings assurance that what we are seeing is indeed HHH coupling
- NB there exist different points of view on this

when would we claim discovery? [5 σ in each of two independent experiments is our gold standard]

- equivalent for an interaction is a bit ambiguous — but better than $\pm 20\%$ determination is probably a reasonable target
- for something of this importance, we may be able to determine the HHH coupling from a combination of N experiments — but this is not a determination by independent experiments
- indirect determination of HHH coupling (e.g. from $gg \rightarrow H \rightarrow \gamma\gamma$ or $gg \rightarrow H \rightarrow ZZ$ or $gg \rightarrow H \rightarrow WW$ or $gg \rightarrow H \rightarrow b\bar{b}$ or $gg \rightarrow H \rightarrow \tau\tau$ or $gg \rightarrow H \rightarrow \mu\mu$ or $gg \rightarrow H \rightarrow e^+e^-$ or $gg \rightarrow H \rightarrow \nu\bar{\nu}$ or $gg \rightarrow H \rightarrow \text{hadrons and leptons...}$)
 - all measurements are indirect
 - single $gg \rightarrow H \rightarrow \gamma\gamma$ or $gg \rightarrow H \rightarrow ZZ$ or $gg \rightarrow H \rightarrow WW$ or $gg \rightarrow H \rightarrow b\bar{b}$ or $gg \rightarrow H \rightarrow \tau\tau$ or $gg \rightarrow H \rightarrow \mu\mu$ or $gg \rightarrow H \rightarrow e^+e^-$ or $gg \rightarrow H \rightarrow \nu\bar{\nu}$ or $gg \rightarrow H \rightarrow \text{hadrons and leptons...}$ are aiming for 5σ discovery
 - but HH & kinematic structure brings assurance that what we are seeing is indeed HHH coupling
- NB there exist different points of view on this

observation of HHH interaction is a “guaranteed discovery” that HEP should be aiming for

Higgs potential

$V(\phi)$, SM

- this is a cartoon
- caution needed: e.g. realistic BSM models do not just modify the potential, but may bring extra scalars (often modify other couplings, but not always, e.g. [2209.00666](#))
- even if we take the picture seriously we may want to consider impact of limited constraints on λ_4 (figures show either SM or FCC-hh constraint; how many coincidences are needed for a BSM model to leave λ_3 untouched while modifying λ_4 ?)

Higgs potential

$V(\phi)$, today

- this is a cartoon
- caution needed: e.g. realistic BSM models do not just modify the potential, but may bring extra scalars (often modify other couplings, but not always, e.g. [2209.00666](#))
- even if we take the picture seriously we may want to consider impact of limited constraints on λ_4 (figures show either SM or FCC-hh constraint; how many coincidences are needed for a BSM model to leave λ_3 untouched while modifying λ_4 ?)

Higgs potential

$V(\phi)$, 2040 (HL-LHC)

- this is a cartoon
- caution needed: e.g. realistic BSM models do not just modify the potential, but may bring extra scalars (often modify other couplings, but not always, e.g. [2209.00666](#))
- even if we take the picture seriously we may want to consider impact of limited constraints on λ_4 (figures show either SM or FCC-hh constraint; how many coincidences are needed for a BSM model to leave λ_3 untouched while modifying λ_4 ?)

Higgs potential

$V(\phi)$, 2060 (FCC-ee, 4IP)

- this is a cartoon
- caution needed: e.g. realistic BSM models do not just modify the potential, but may bring extra scalars (often modify other couplings, but not always, e.g. [2209.00666](#))
- even if we take the picture seriously we may want to consider impact of limited constraints on λ_4 (figures show either SM or FCC-hh constraint; how many coincidences are needed for a BSM model to leave λ_3 untouched while modifying λ_4 ?)

Higgs potential

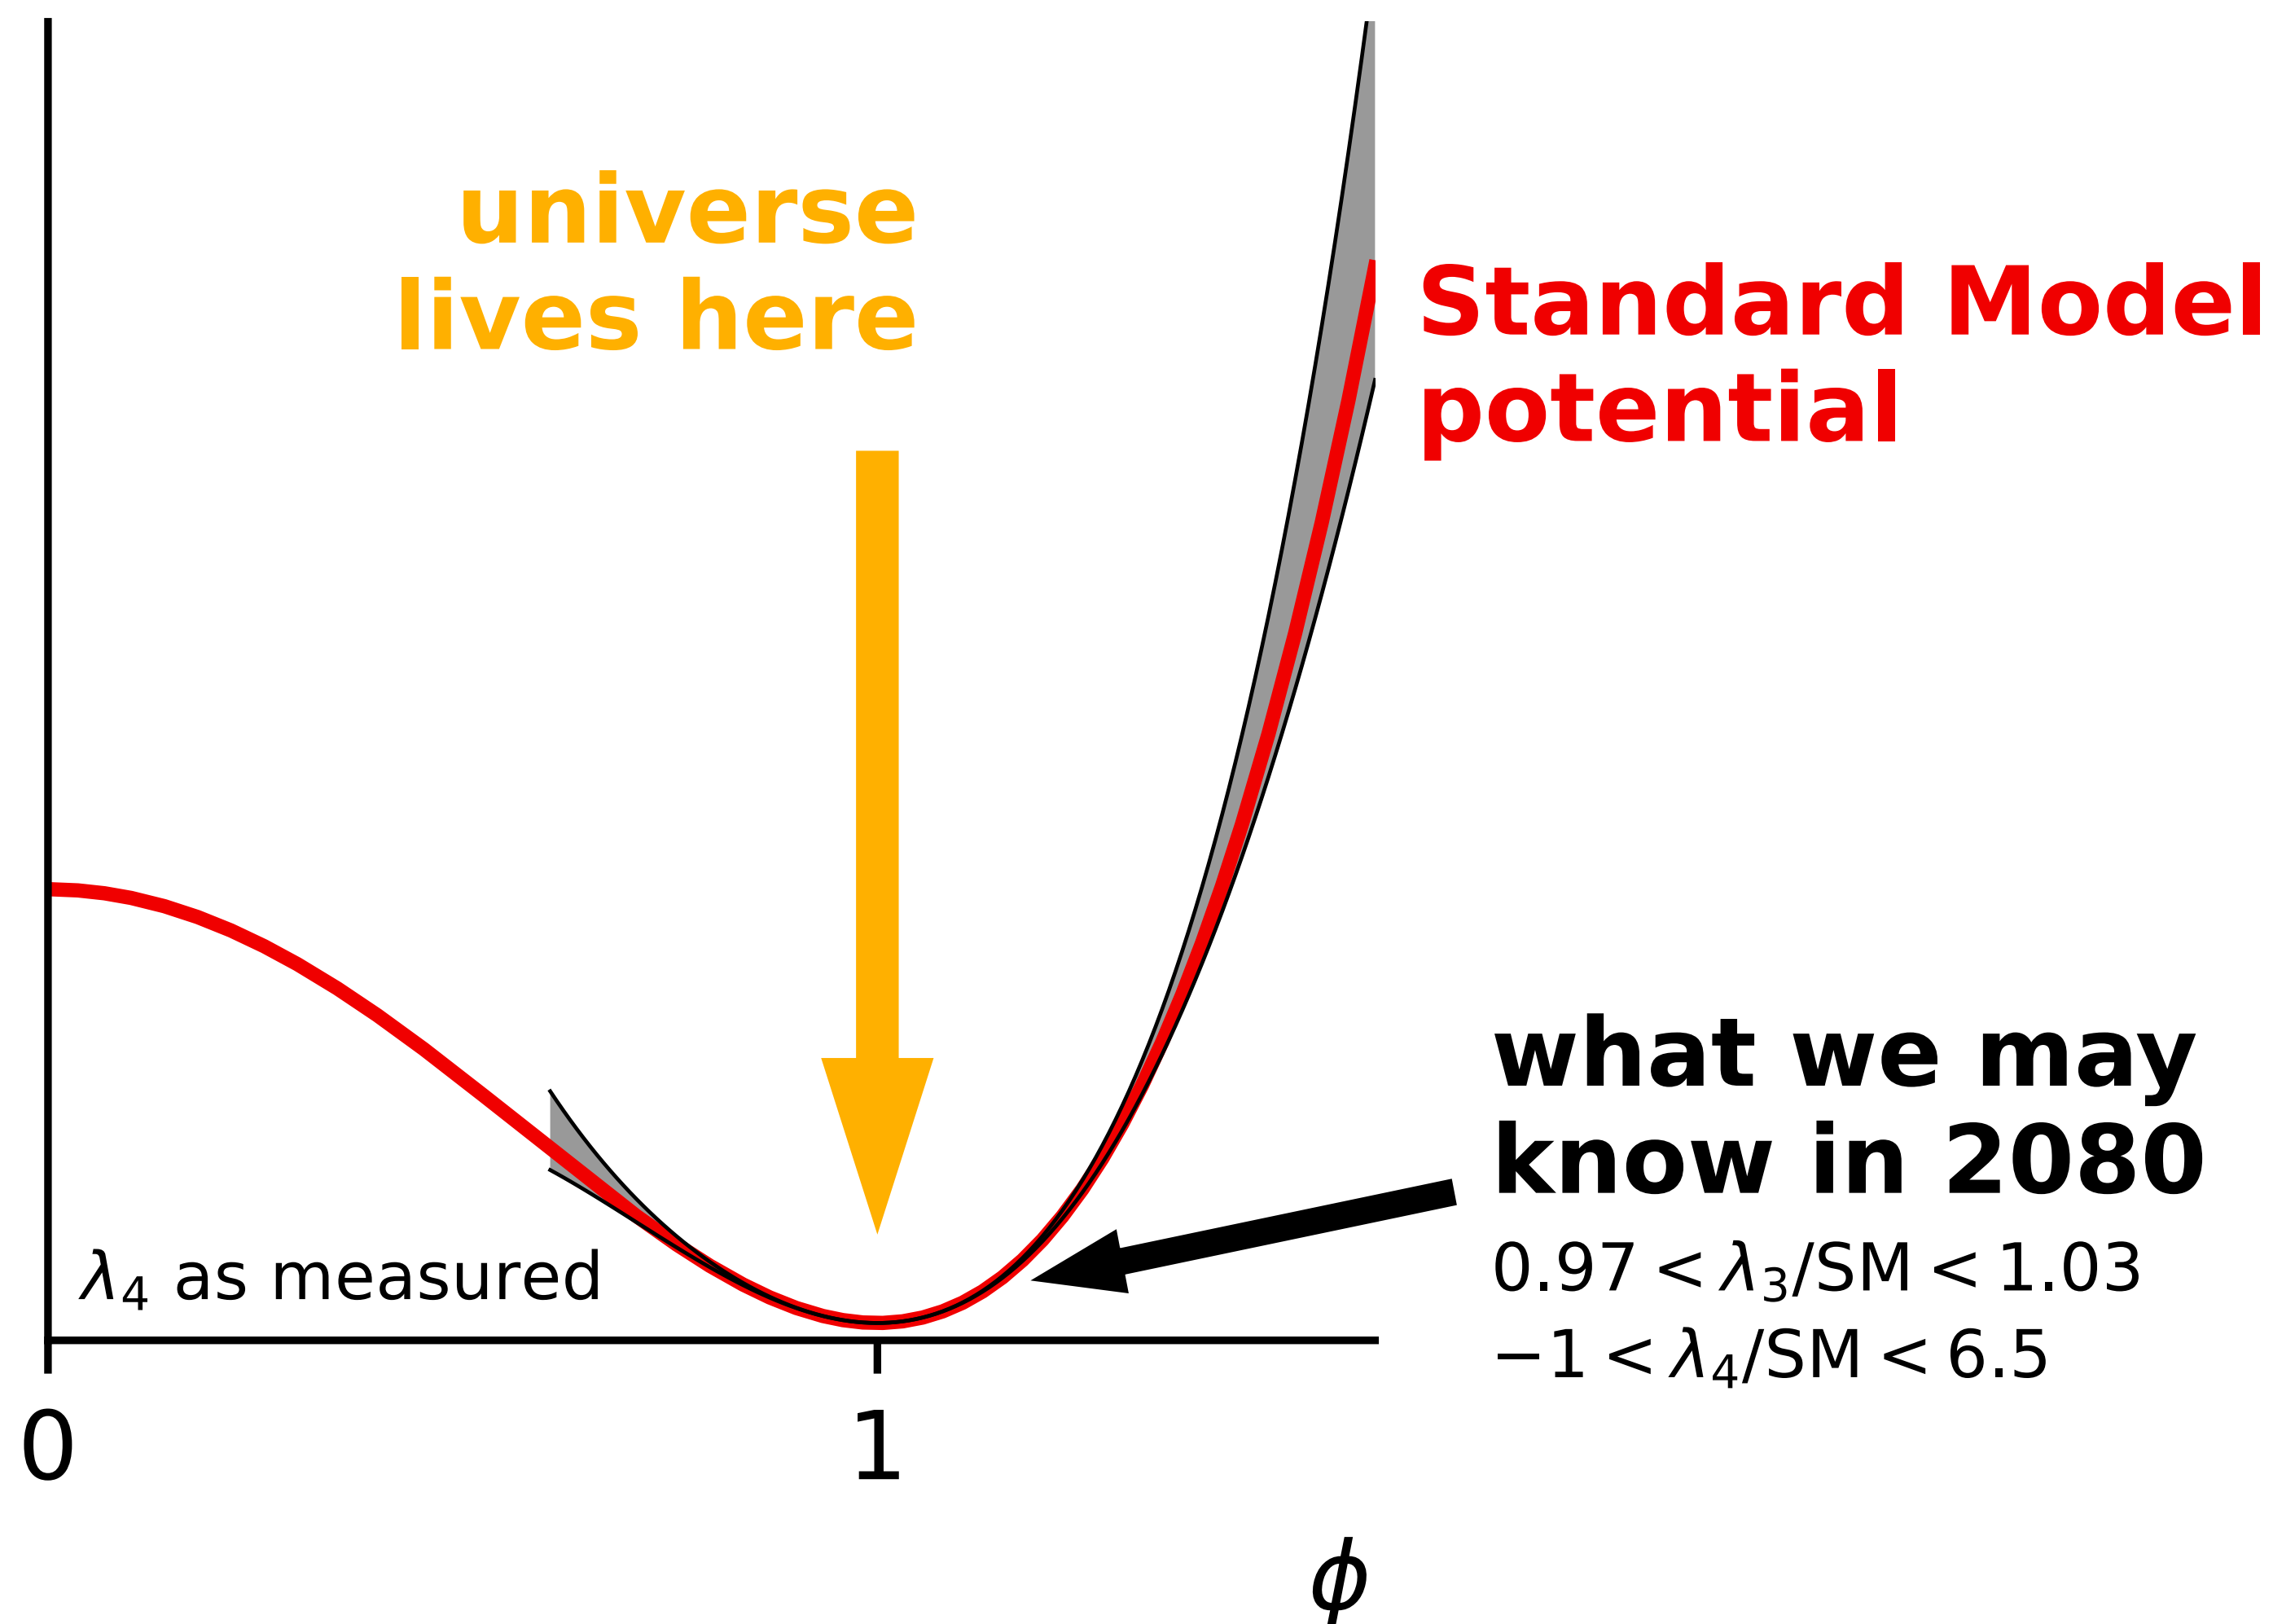

$V(\phi)$, 2080 (FCC-hh)

- this is a cartoon
- caution needed: e.g. realistic BSM models do not just modify the potential, but may bring extra scalars (often modify other couplings, but not always, e.g. [2209.00666](#))
- even if we take the picture seriously we may want to consider impact of limited constraints on λ_4 (figures show either SM or FCC-hh constraint; how many coincidences are needed for a BSM model to leave λ_3 untouched while modifying λ_4 ?)

Higgs potential

$V(\phi)$, 2080 (FCC-hh)+ κ_4 (direct)

- this is a cartoon
- caution needed: e.g. realistic BSM models do not just modify the potential, but may bring extra scalars (often modify other couplings, but not always, e.g. [2209.00666](#))
- even if we take the picture seriously we may want to consider impact of limited constraints on λ_4 (figures show either SM or FCC-hh constraint; how many coincidences are needed for a BSM model to leave λ_3 untouched while modifying λ_4 ?)

desirable features of the next major HEP project(s)?

an important target to be reached ~ guaranteed discovery

exploration into the unknown by a significant factor in energy

major progress on a broad array of particle physics topics

likelihood of success, robustness (e.g. multiple experiments)

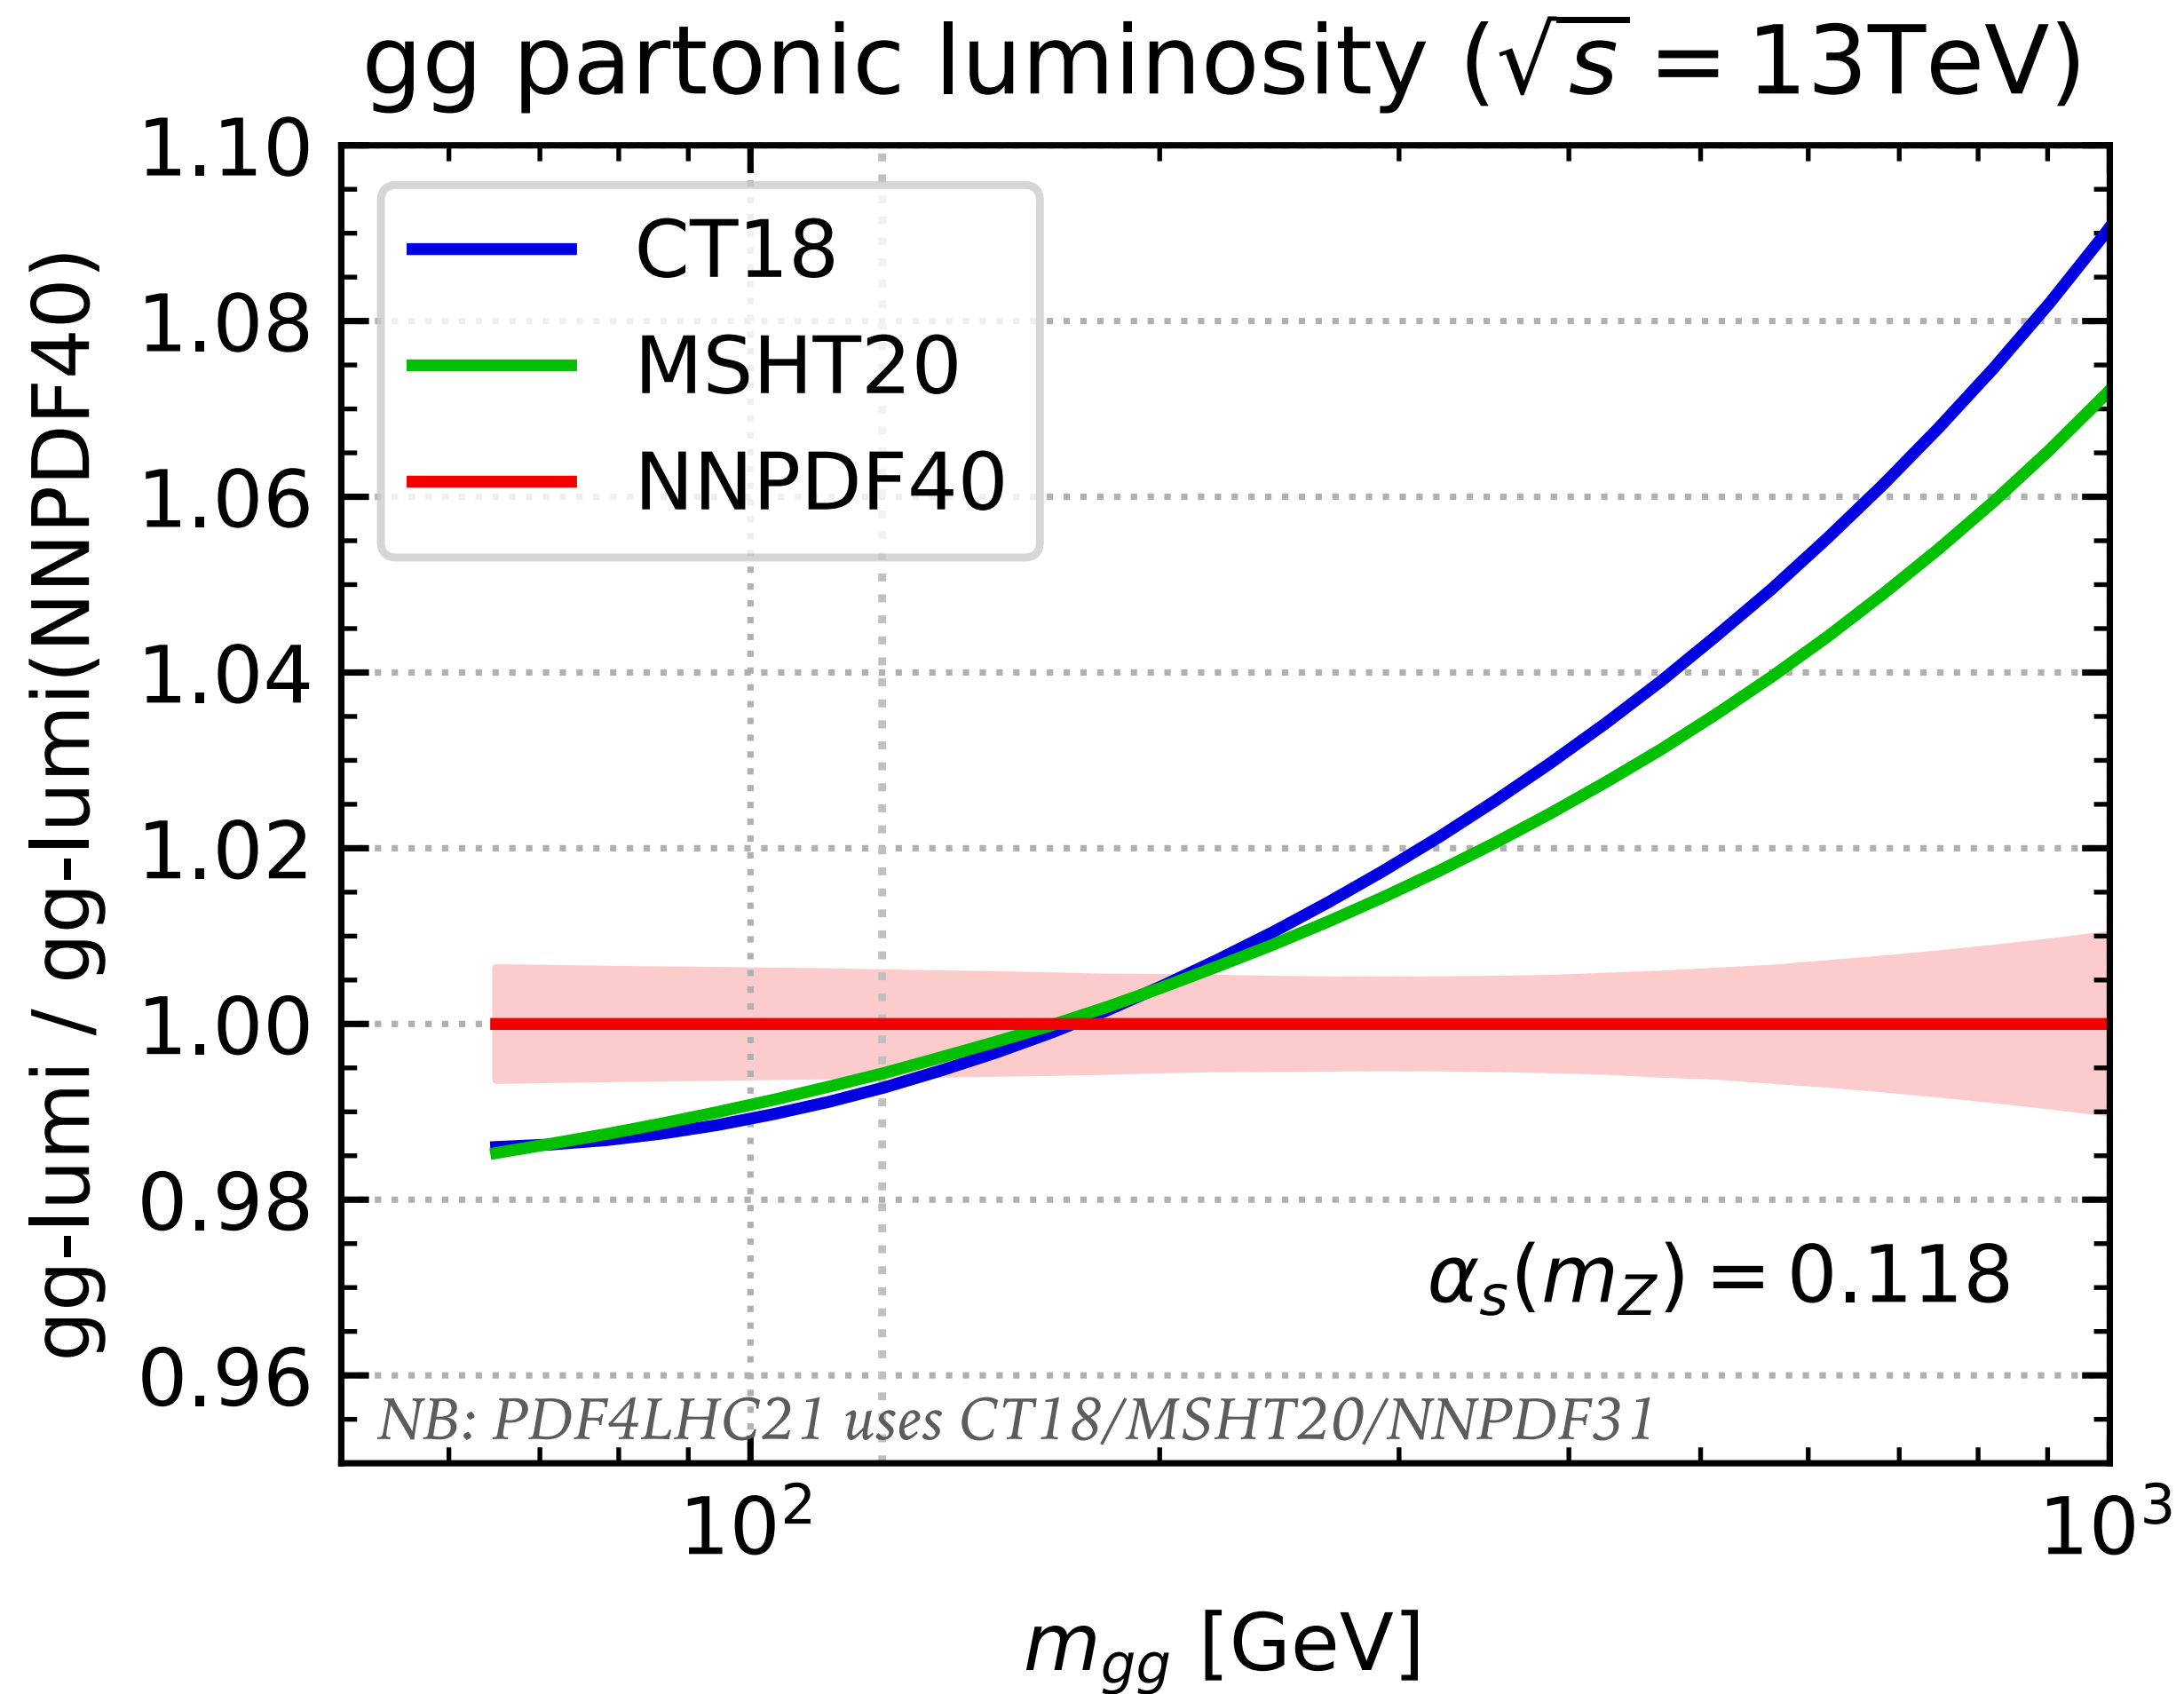

cost-effective construction & operation,
low carbon footprint, novel technologies

m_W measurements

do you believe the measurement when it **disagrees**
with your expectations?

we don't know the precision limit of hadron colliders — but we may be close to reaching it

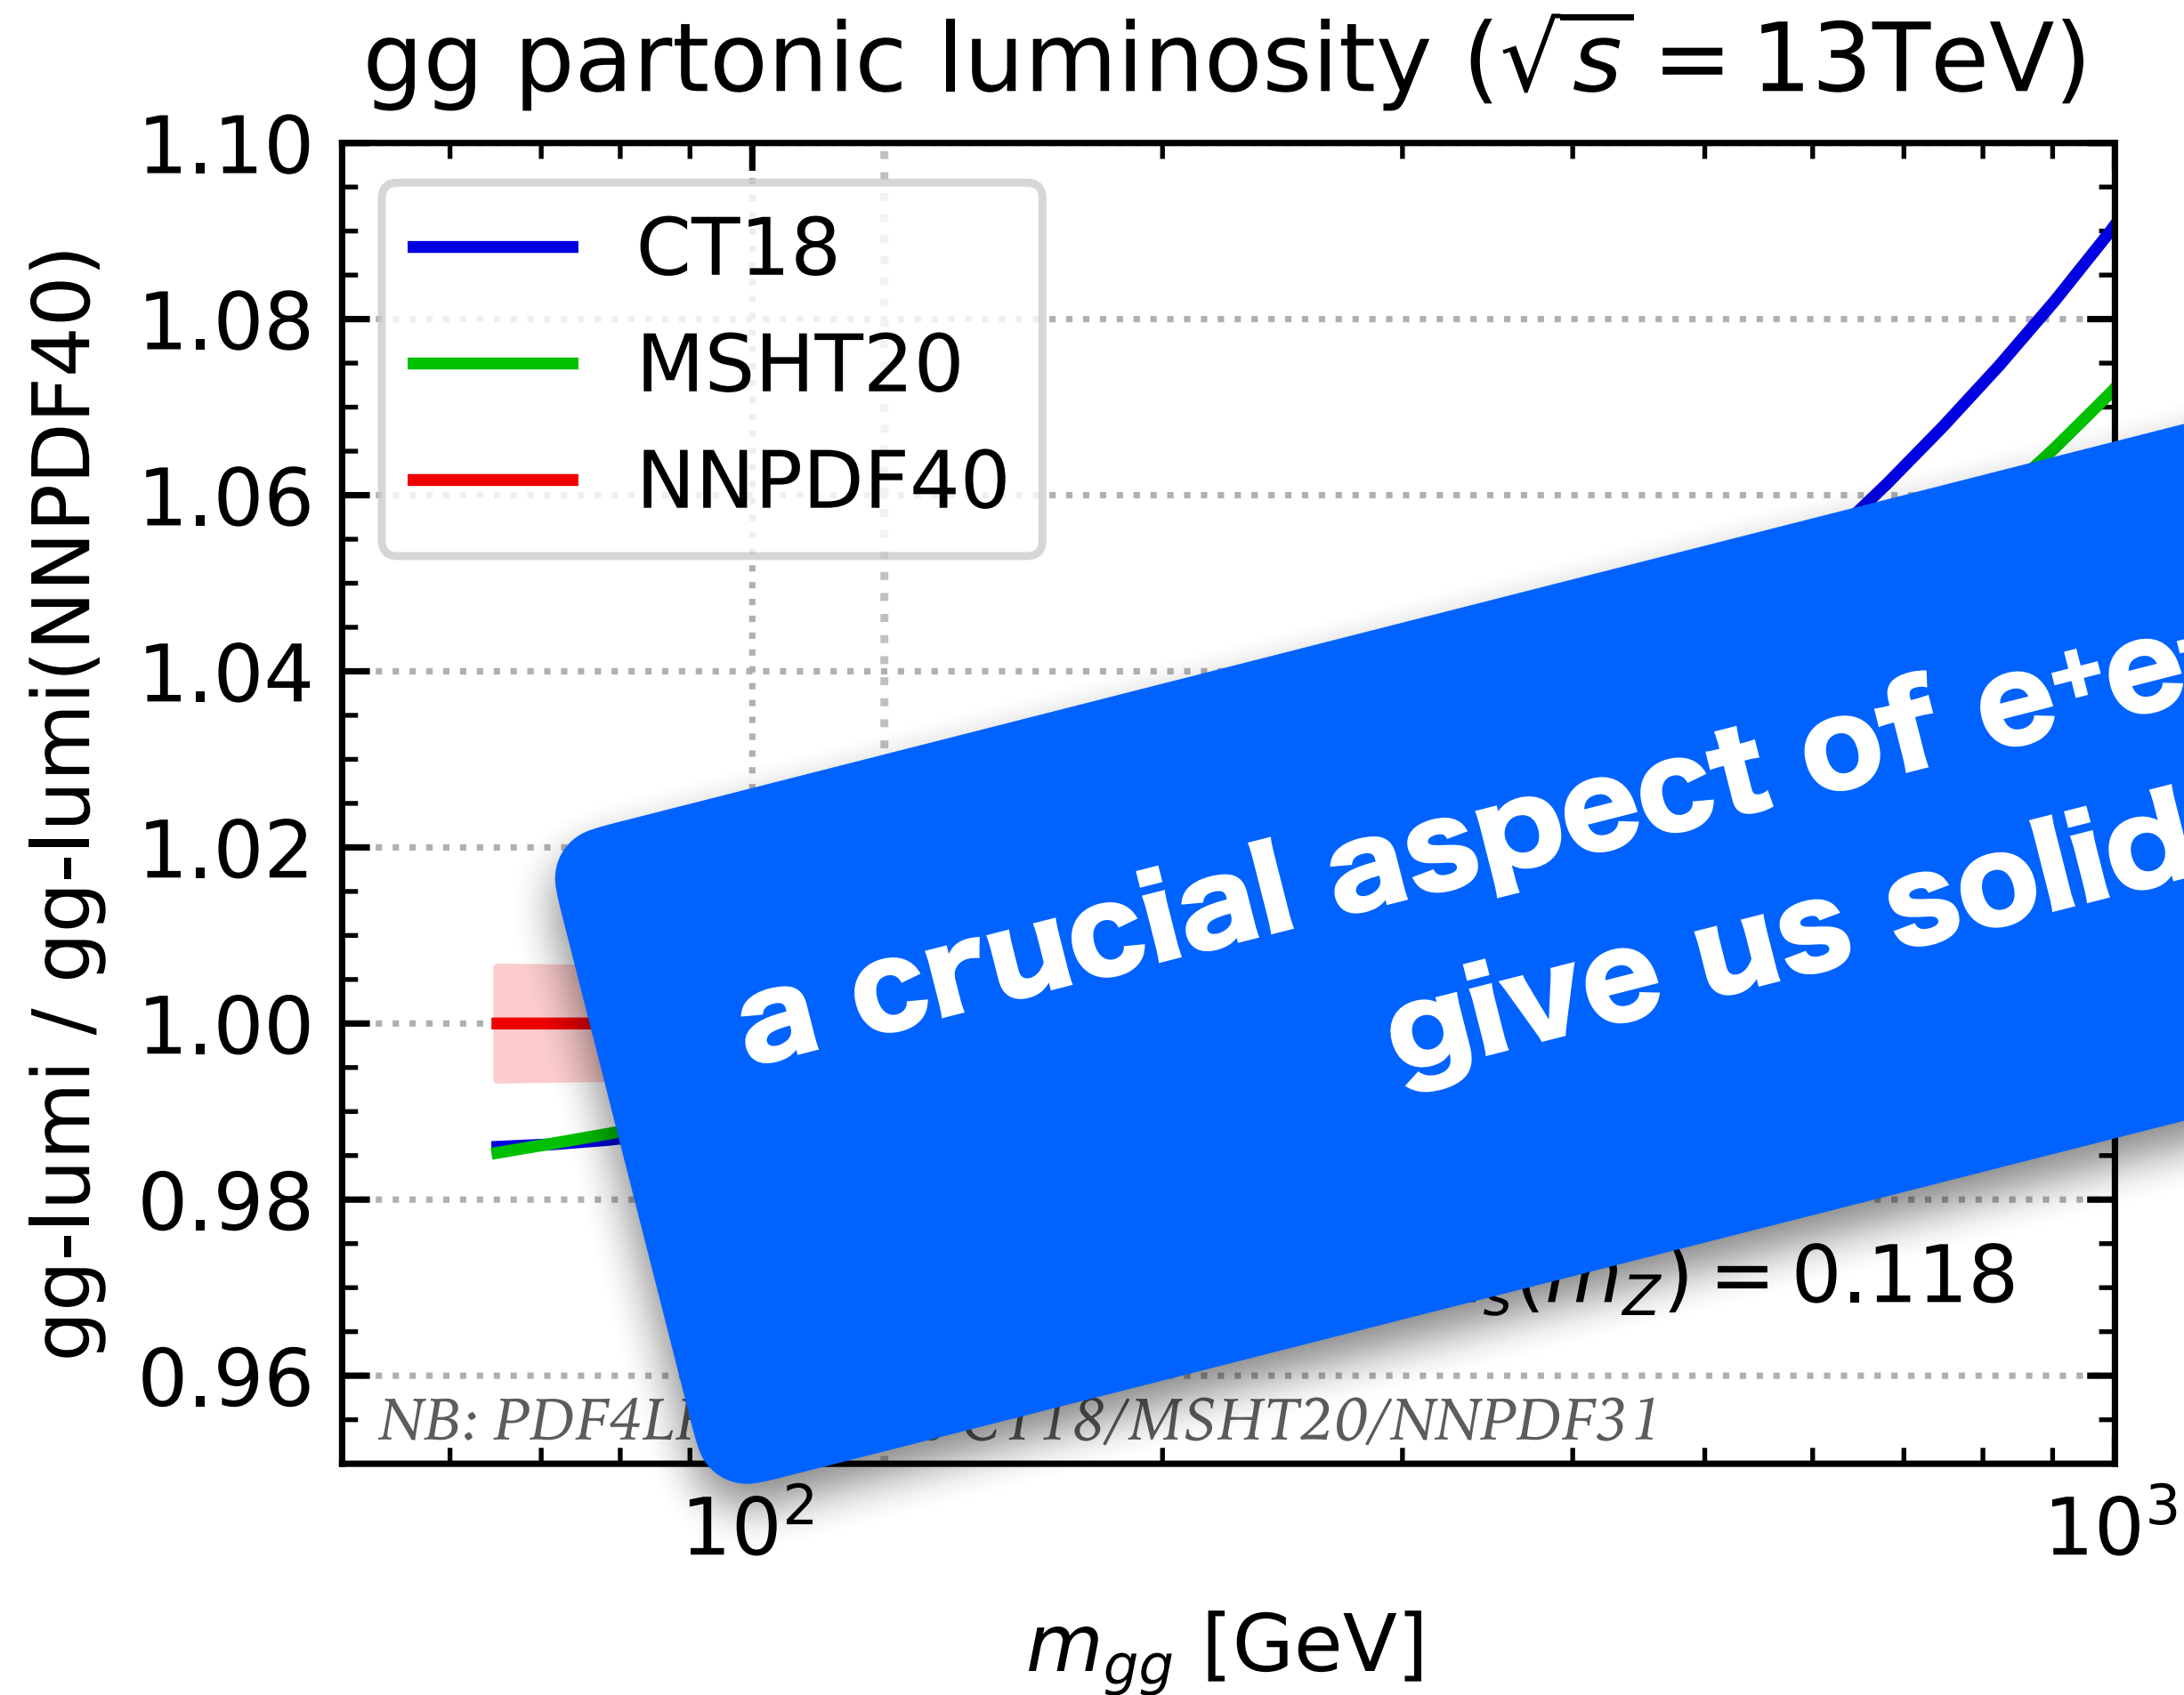

gg-lumi, ratio to PDF4LHC15 @ m_H

PDF4LHC15	1.0000	\pm	0.0184	
PDF4LHC21	0.9930	\pm	0.0155	
CT18	0.9914	\pm	0.0180	$\times 3$
MSHT20	0.9930	\pm	0.0108	
NNPDF40	0.9986	\pm	0.0058	

Parton Distribution Functions are one of several elements that may limit LHC/FCC-hh precision:

- essential for hadron-collider interpretation
- PDF fits are complex, e.g. involve (sometimes inconsistent) data, some of it close to non-perturbative scale
- only partial understanding of their limits

we don't know the precision limit of hadron colliders — but we may be close to reaching it

a crucial aspect of e^+e^- colliders is that they give us solid foundations

Parton Distribution Functions are one of several elements that may limit LHC/FCC-hh precision:

- essential for hadron-collider interpretation
- PDF fits are complex, e.g. involve (sometimes inconsistent) data, some of it close to non-perturbative scale
- only partial understanding of their limits

desirable features of a worldwide HEP project?

an important target that is guaranteed to be reached
(no-lose theorem)

exploration into the unknown by a significant factor in energy

major progress on a broad array of particle physics topics

likelihood of success, robustness (incl. multiple experiments)

cost-effective construction & operation, low carbon footprint

what should we expect as a step up in energy?

I like the Z'_{SSM} as a simple measure of progress
(perhaps not very “exciting”, but simple and most experiments look for it)

Tevatron

$p\bar{p}$, 1.96 TeV, 10 fb⁻¹

Exclusion limit ~ 1.2 TeV

(if they had analysed all their data in
electron and muon channels; actual CDF
limit 1.071 TeV, 4.7fb⁻¹, $\mu\mu$ only)

× 5.6
→

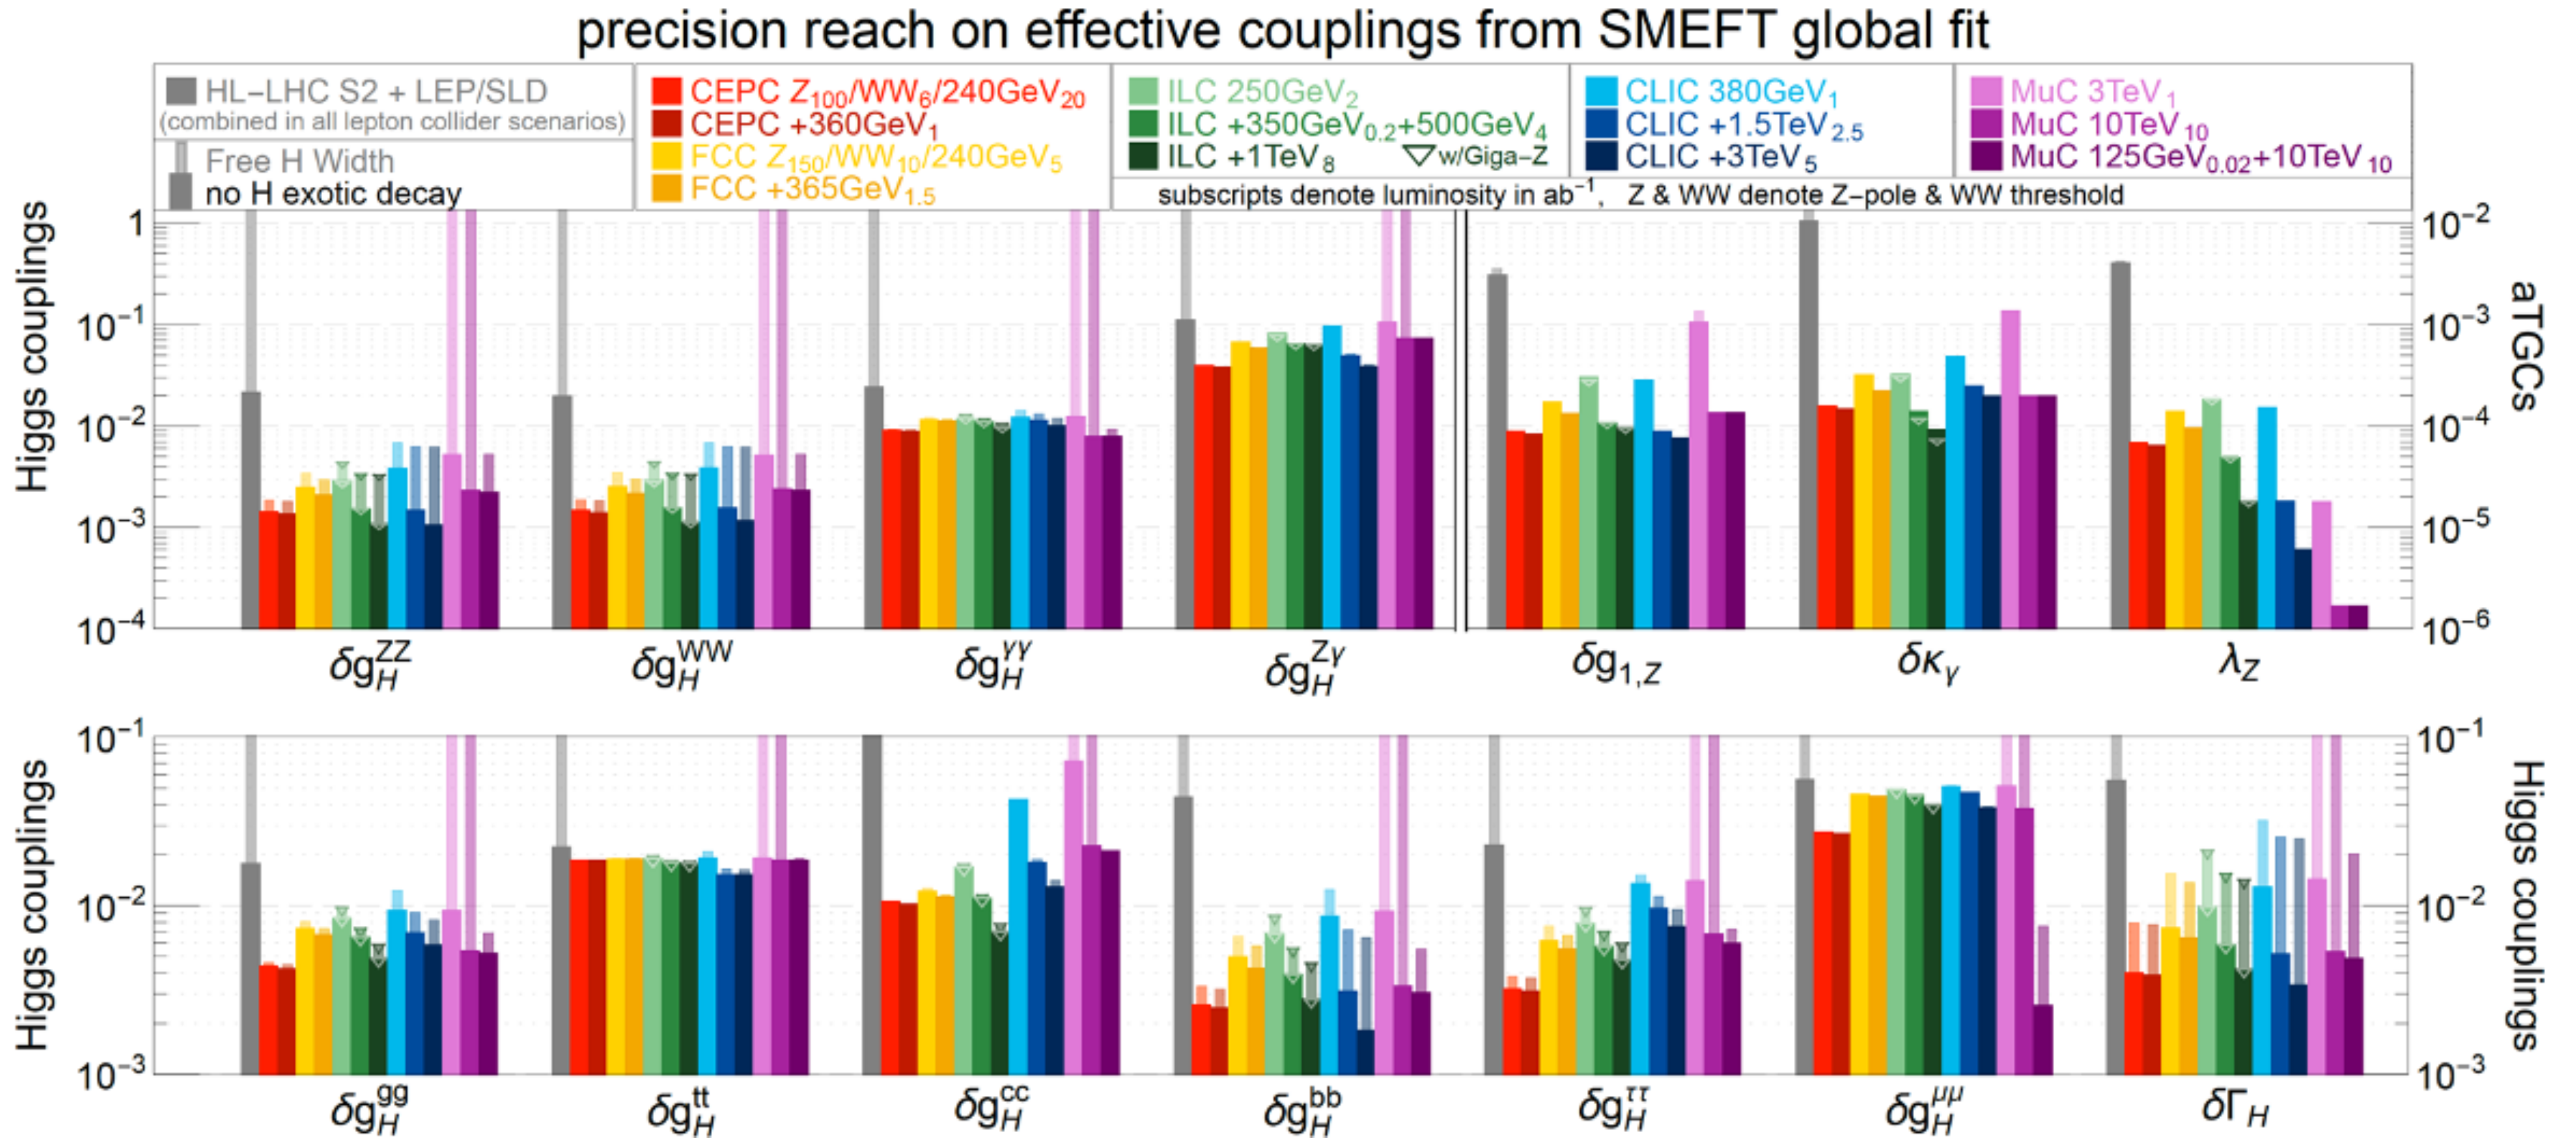

LHC

pp , 14 TeV, 3000 fb⁻¹

Exclusion limit ~ 6.7 TeV

(electron and muon channels,
single experiment)

increase in precision

<https://arxiv.org/abs/2206.08326>

increase in precision is like $\times 4 - 5$ increase in energy reach

95% CL scale limits on 4-fermion contact interactions from O_{2B}

<https://arxiv.org/abs/2206.08326>

step up in energy for direct searches?

I like the Z'_{SSM} as a simple measure of progress
(perhaps not very “exciting”, but simple and most experiments look for it)

LHC
pp, 13 TeV, 3000 fb⁻¹

Exclusion limit ~ 6.7 TeV

(electron and muon channels,
single experiment)

FCC-hh
pp, 100 TeV, 20 ab⁻¹

Exclusion limit ~ 41 TeV

(based on PDF luminosity scaling,
assuming detectors can handle muons
and electrons at these energies)

step up in energy for direct searches?

I like the Z'_{SSM} as a simple measure of progress
(perhaps not very “exciting”, but simple and most experiments look for it)

LHC
pp, 13 TeV, 3000 fb⁻¹

Exclusion limit ~ 6.7 TeV

(electron and muon channels,
single experiment)

× 6.4 →

SppC
125 TeV, 5 ab⁻¹

Exclusion limit ~ 43 TeV

(based on PDF luminosity scaling,
assuming detectors can handle muons
and electrons at these energies)

desirable features of the next major HEP project(s)?

an important target to be reached ~ guaranteed discovery

exploration into the unknown by a significant factor in energy

major progress on a broad array of particle physics topics

likelihood of success, robustness (e.g. multiple experiments)

cost-effective construction & operation,
low carbon footprint, novel technologies

illustration is for FCC — but message is comparable for other colliders

conclusions

Conclusions

- There is a **guaranteed discovery**: directly establishing Higgs self-interaction, which holds the SM together, via robust precision of Higgs factory and direct measurement at higher-energy colliders
 - is there a chance of a second no-lose theorem in establishing (or disproving) SM origin of electron mass at circular e^+e^- colliders?
- The **step up in energy reach** that we expect is $\sim \times 4 - 5$
 - e^+e^- colliders deliver that mostly in “indirect” sensitivity, through precision increase $\sim \times 18$
 - FCC-hh/SppS deliver that in direct search sensitivity (muon collider does for some scenarios)
- **Diversity and robustness of the programme** = essential part of their strength

PHYSICS WITH A MULTI-TeV HADRON COLLIDER

C.H. Llewellyn Smith,

Looking at the wide variety of alternatives which have been proposed, it might appear that theorists are in disarray but it seems to me that the present situation is an inevitable consequence of the successes of the 1970's. The problems of the 1960's - the nature of hadrons, the nature of the strong force, the nature of the weak force - have been solved. We now confront deeper problems - the origin of mass, the choice of fundamental building blocks (the problem of flavour), the question of further unification of forces including gravity, the origin of charge and of gauge symmetry. It is only to be expected that many of the first attempts to grapple with these problems will be misguided. As ever, we must reply on experiment to reveal the truth.

improvements of up to

 $\times 14-18$

It's not inconceivable that the top mass could be sufficiently mis-measured at hadron colliders that the SM-universe is stable all the way to the Planck scale

condition in terms of the pole top mass. We can express the stability condition of eq. (64) as

$$M_t < (171.53 \pm 0.15 \pm 0.23_{\alpha_3} \pm 0.15_{M_h}) \text{ GeV} = (171.53 \pm 0.42) \text{ GeV}. \quad (66)$$

arXiv:1307.3536

Searches at muon collider

Plots being shown suggest:
 4 TeV muon collider beats a
 100 TeV pp collider
 in searches for new physics.

Useful to nuance the statement:

- 100 TeV pp, 20 ab⁻¹ can discover Z' up to $m_{Z'} \sim 38$ TeV
- For $\mu\mu$ collider to discover Z' at $m_{Z'} \sim 38$ TeV, it needs $\sqrt{s} \sim 38$ TeV (with lower \sqrt{s} you would see deviation from SM, but not know what it is)
- However a 38 TeV muon collider would be much better at studying the Z' than the 100 TeV pp machine
