Towards an understanding of jet substructure

14 May 2014

Gavin Salam (CERN) based on work with Dasgupta, Fregoso & Marzani Albert-Ludwigs-Universität Freiburg

Broad Context

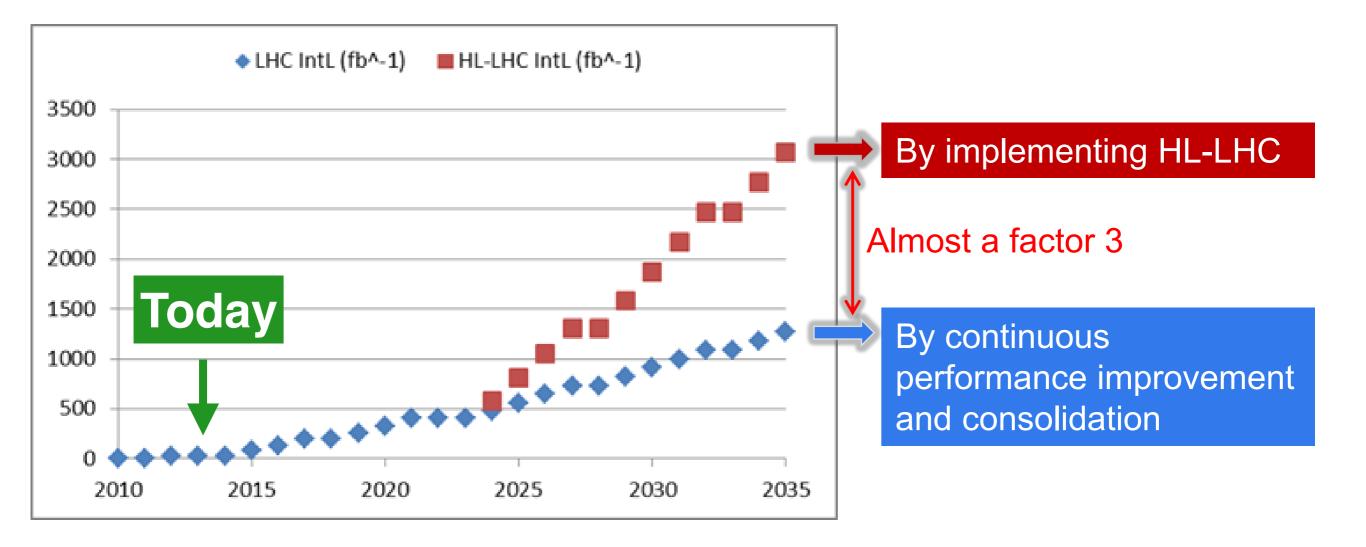

(after 3 years of LHC operation at 7 & 8 TeV)

Higgs discovered Nothing Beyond Standard Model (BSM) so far, with many limits now well above 1 TeV Standard Model measurements Surprises in heavy-ion (and pA) collisions

What is programme for coming years?

Investigate Higgs in fine detail Push BSM search much further (including through flavour physics) Highly precise Standard Model measurements Continue the study of heavy ions

Only at the start of a long programme in 2015 almost double the energy → 13–14 TeV over 20 years: 150 times more data

Even longer term – a 100 TeV collider?

Facility	Ring (km)	Magnets (T)	√s (TeV)	
(SSC)	87	6.6	40	
LHC	27	8.3	14	
HE-LHC	27	16-20	26-33	
FHC	80 80 100	8.3 20 15	42 100 100	LHC (14 TeV)
		Image: bit of the state of the st		d d d d d d d d d d d d d d d d d d d

These are endeavours involving ~10,000 people What are the roles of theorists?

Devising models of new physics, to be searched for

Predicting the structure of events, cross sections

Establishing the implications of existing data (for new physics, for the Standard Model)

Thinking of new ways to exploit the data → this talk, specifically with jets Jets – collimated energetic particle bunches quark date back to the late 1970s

anti-quark

Jets — collimated energetic particle bunches date back to the late 1970s

Jets — collimated energetic particle bunches date back to the late 1970s

Sterman and Weinberg, Phys. Rev. Lett. **39**, 1436 (1977):

To study jets, we consider the partial cross section $\sigma(E,\theta,\Omega,\varepsilon,\delta)$ for e⁺e⁻ hadron production events, in which all but a fraction $\varepsilon <<1$ of the total e⁺e⁻ energy E is emitted within some pair of oppositely directed cones of half-angle $\delta <<1$, lying within two fixed cones of solid angle Ω (with $\pi\delta^2 <<\Omega <<1$) at an angle θ to the e⁺e⁻ beam line. We expect this to be measur-

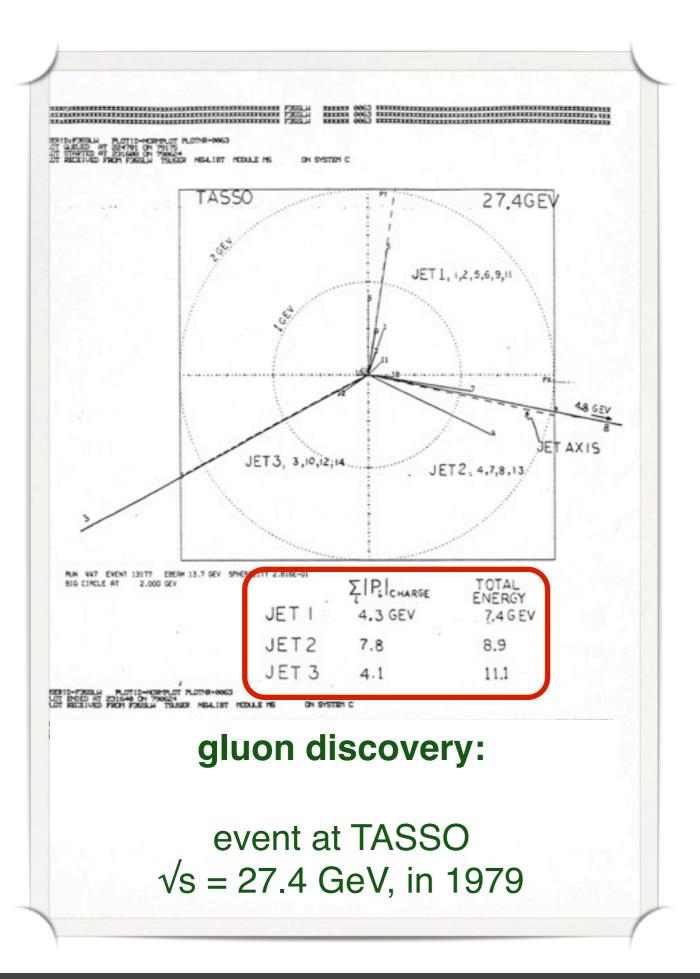

$$\sigma(\mathbf{E},\theta,\Omega,\varepsilon,\delta) = \left(\frac{d\sigma}{d\Omega}\right)_{0}\Omega\left[1 - \left(\frac{g_{\rm E}^{2}}{3\pi^{2}}\right)\left\{3\ln\delta + 4\ln\delta\ln2\varepsilon + \frac{\pi^{3}}{3} - \frac{5}{2}\right\}\right]$$

R

Jets — collimated energetic particle bunches date back to the late 1970s

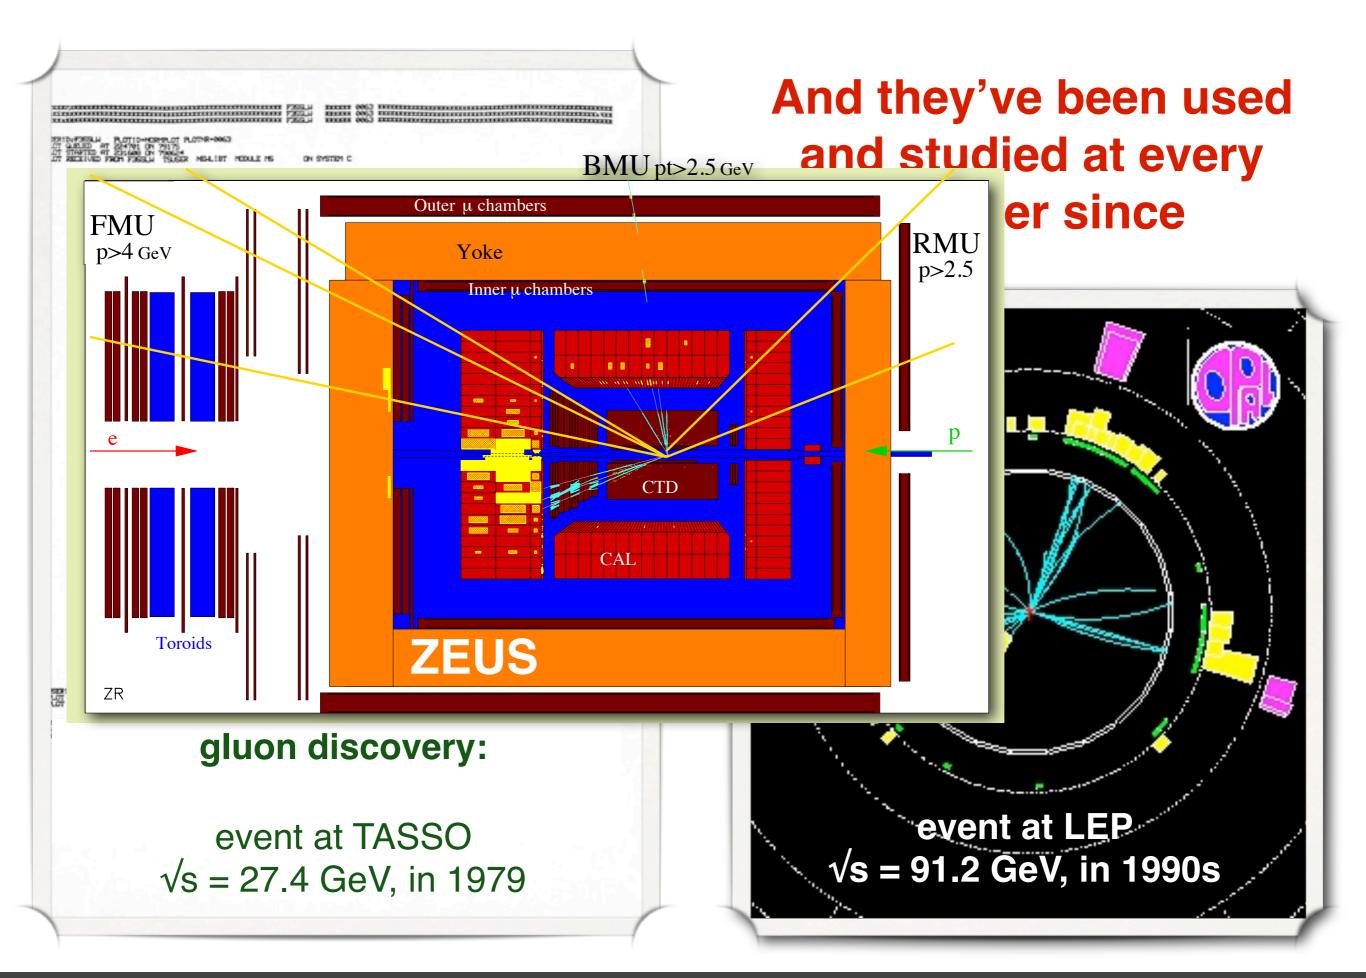

R

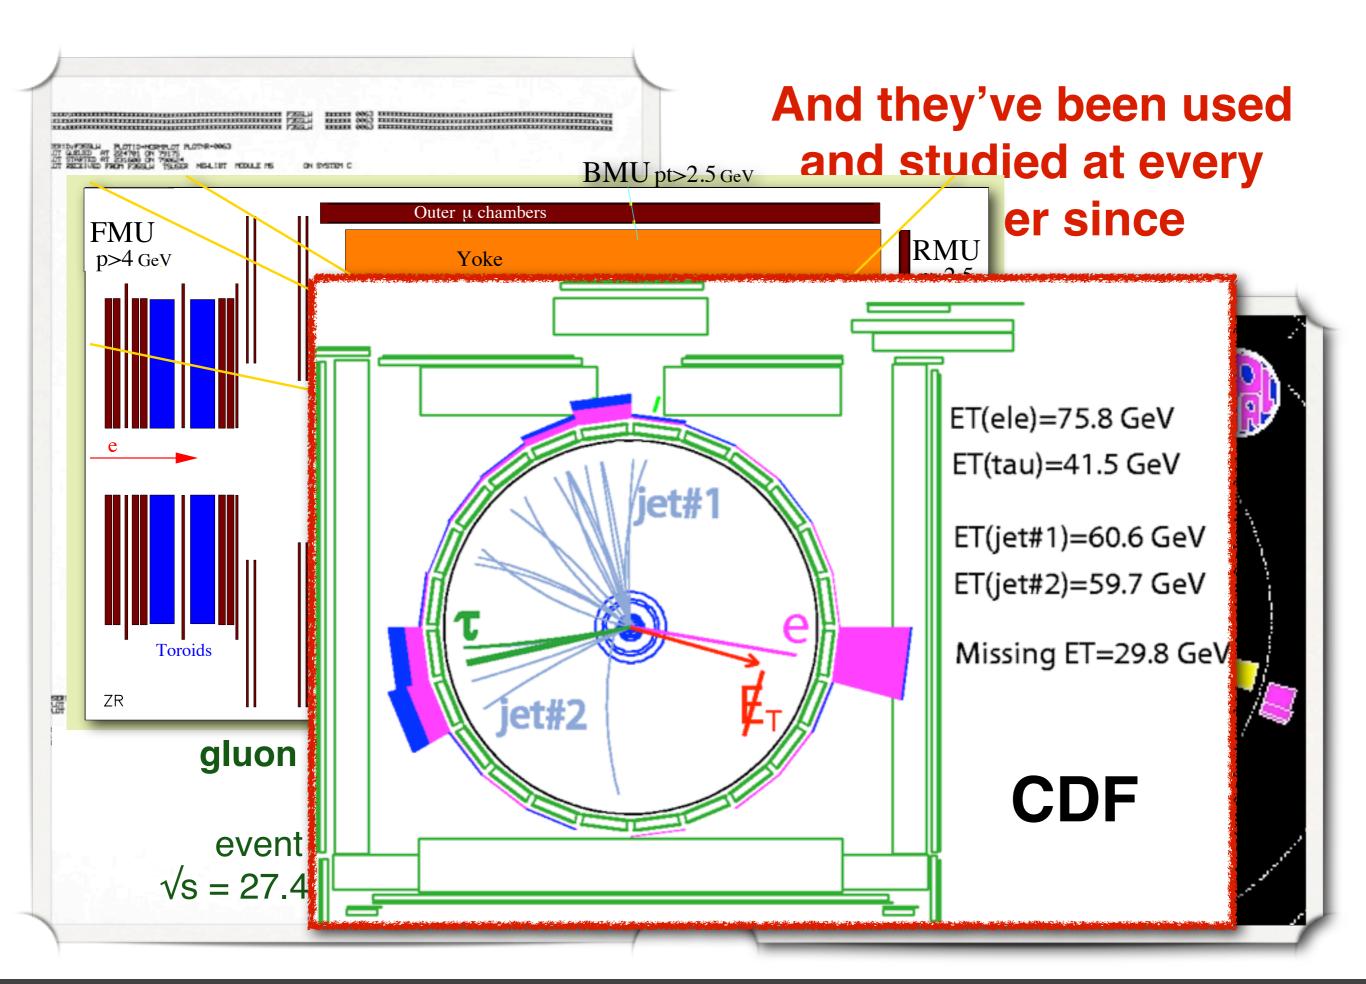

For many uses, jets, still today, effectively "measured" by capturing radiation with a cone of ~ fixed opening angle **R**

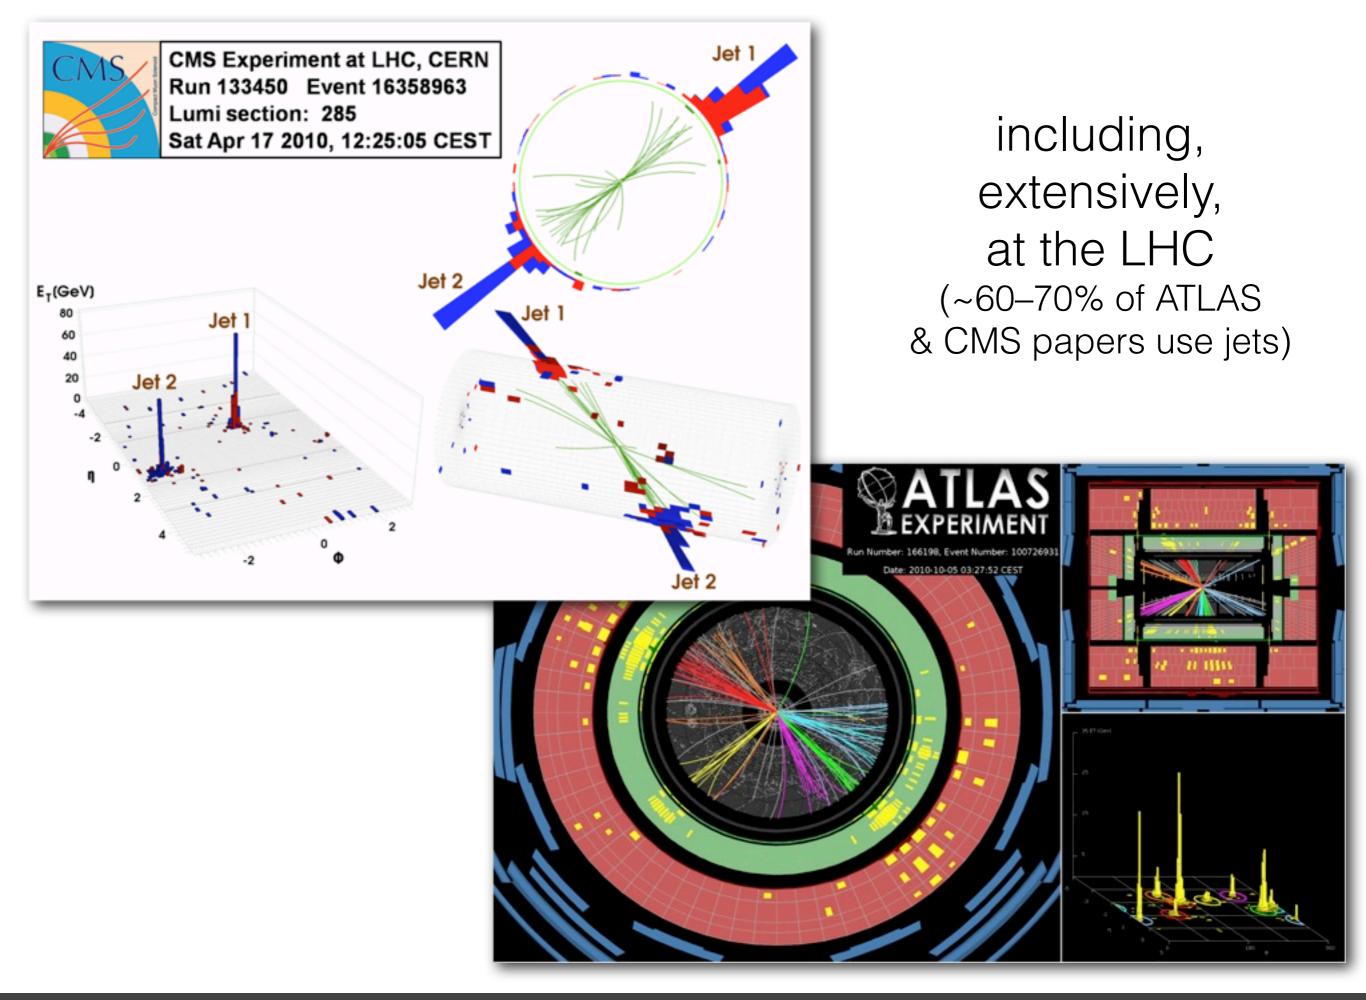

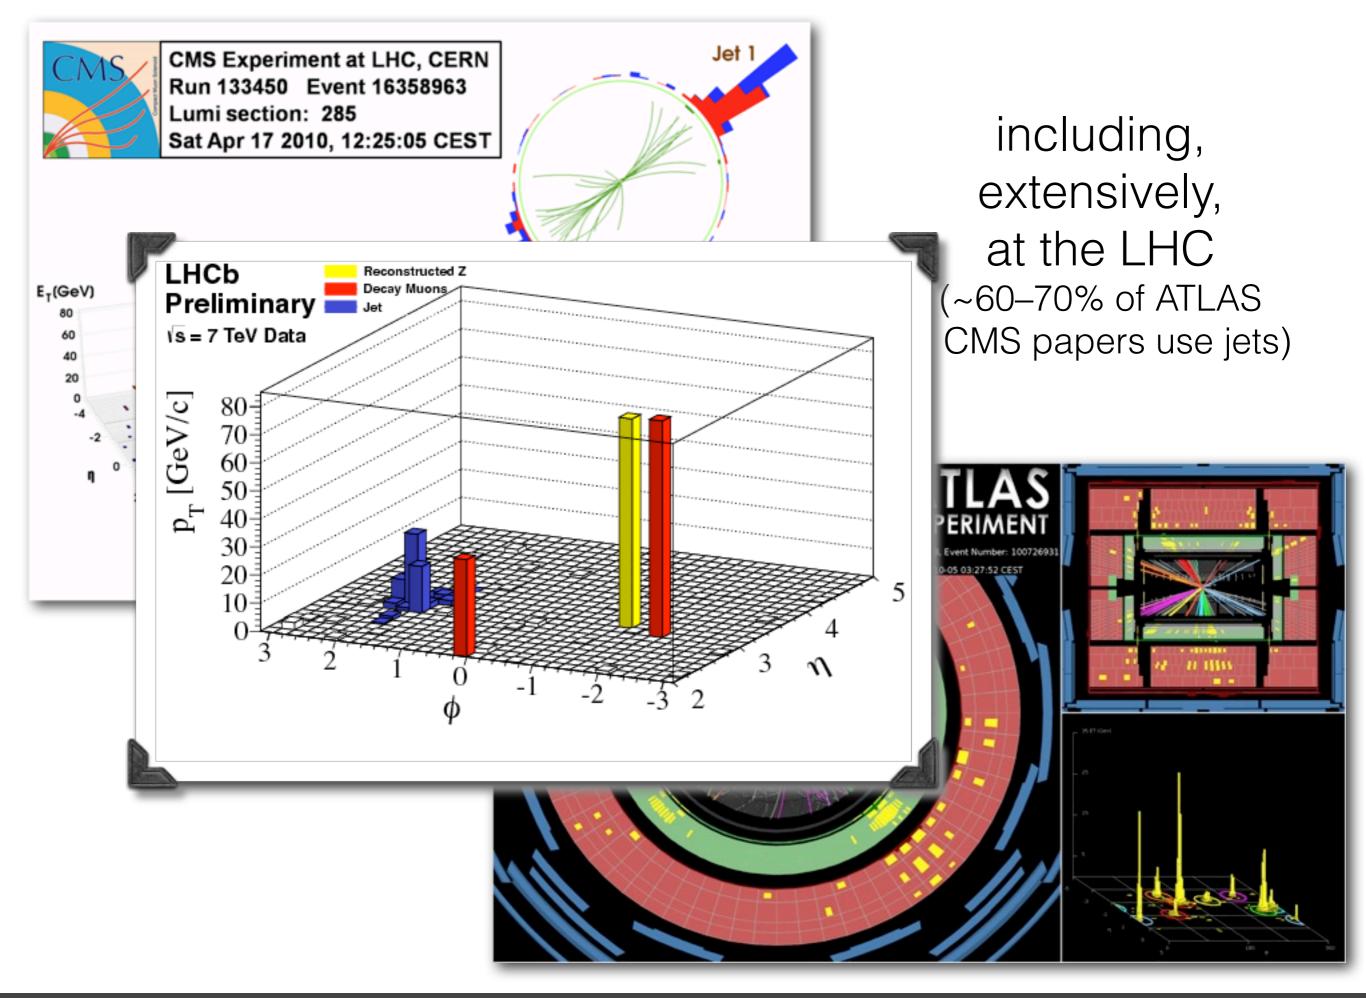

And they've been used and studied at every collider since

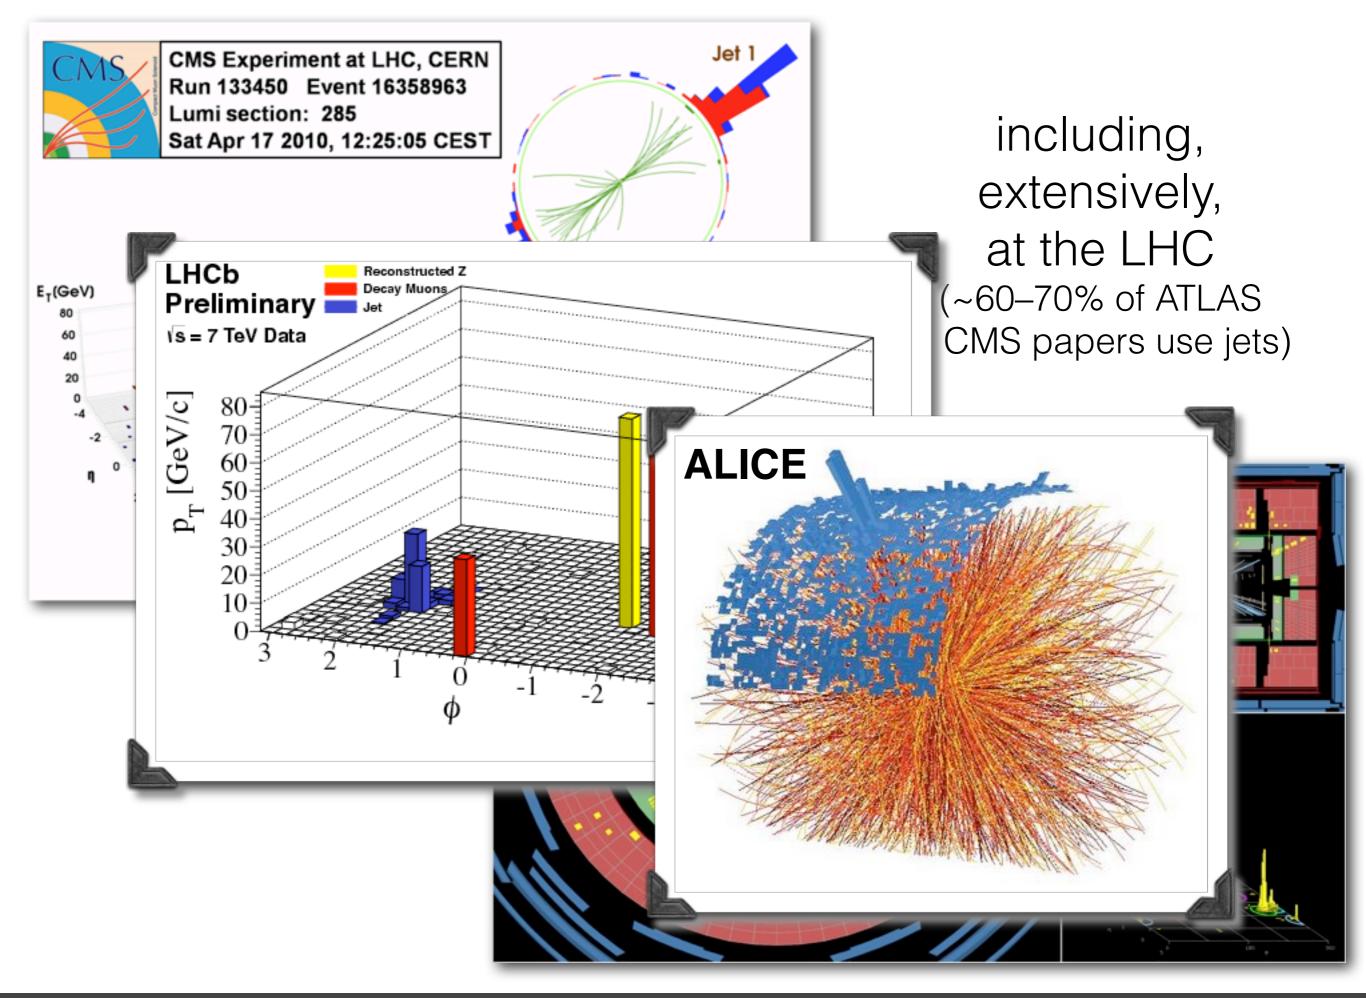

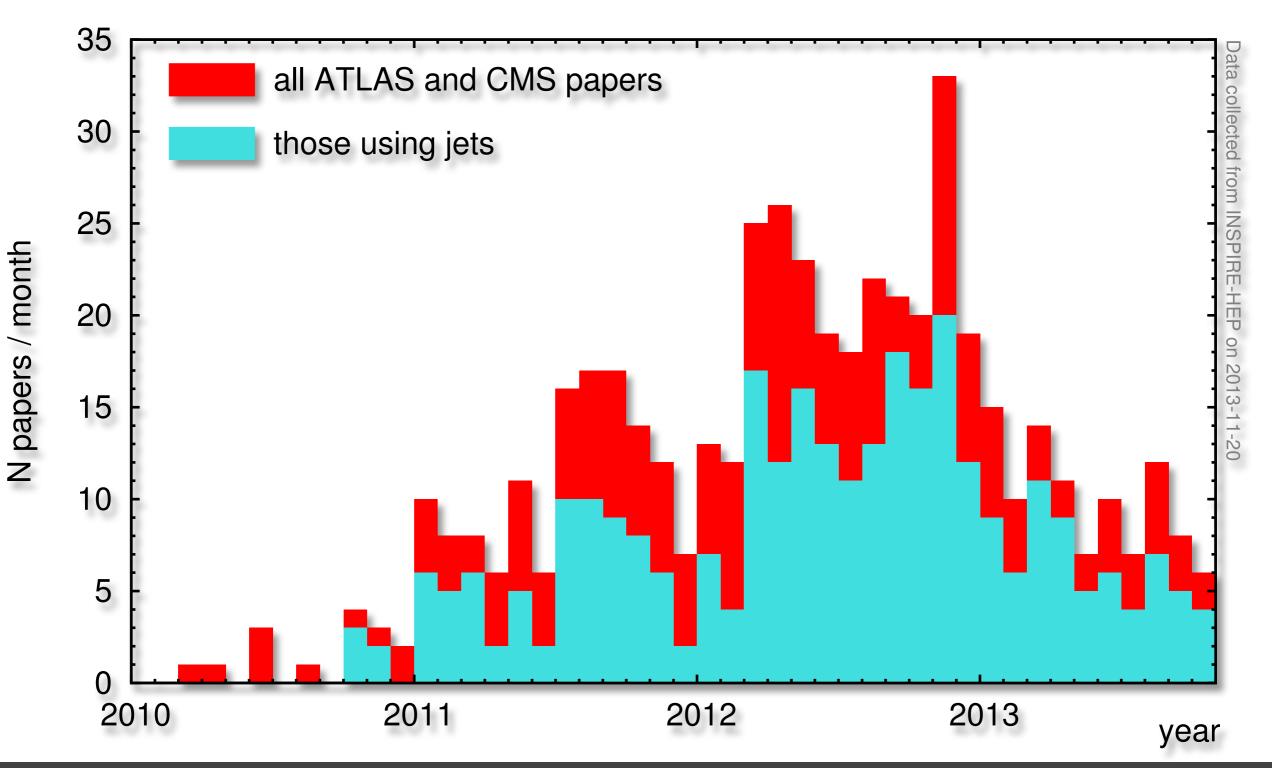

60-70% of recent ATLAS and CMS papers use jets in their analyses, i.e. any time they want a quark or gluon to be present (or absent) in an event

Most LHC jet uses fall under the (historical) category

"a jet is basically a parton"

e.g. from a heavy-object decay, ISR, etc.

If radiation is modelled correctly in the Monte Carlos, most experimenters don't even need to think (much) about jets. Just build on standard jet tools: FastJet (Cacciari, GPS, Soyez '05–'14), anti-k_t (idem '08), area subtraction of pileup (idem, '06–'12) and the hard work of experimental calibration

Most LHC jet uses fall under the (historical) category

"a jet is basically a parton"

e.g. from a heavy-object decay, ISR, etc.

If radiation is modelled correctly in the Monte Carlos, most experimenters don't even need to think (much) about jets. Just build on standard jet tools: FastJet (Cacciari, GPS, Soyez '05–'14), anti-k_t (idem '08), area subtraction of pileup (idem, '06–'12) and the hard work of experimental calibration

But as LHC moves to search "harder" for new physics, we start to need to push analyses to their boundary, e.g.

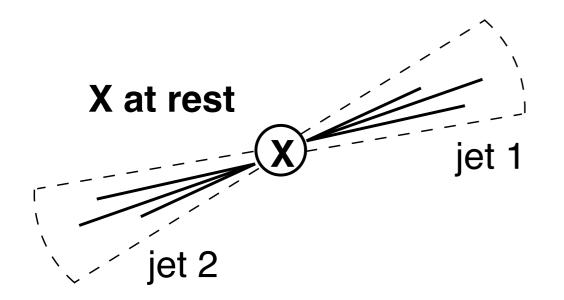

Enhance sensitivity to small signal/background Explore very highest pt's Learn how to handle complex final states

→ for that, you need advanced jet techniques

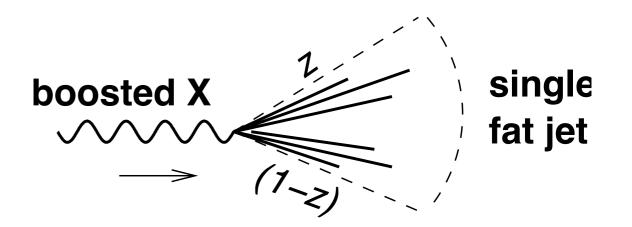

Boosted hadronic decays

(X = W, Z, H, top, new particle)

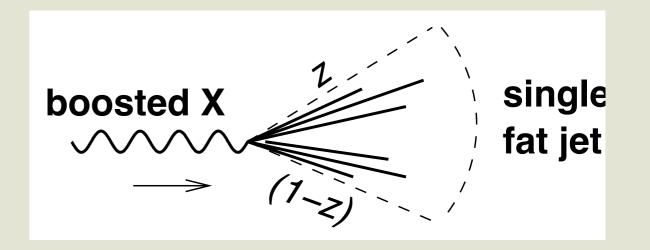

Normal analyses: two quarks from $X \rightarrow q\bar{q}$ reconstructed as two jets

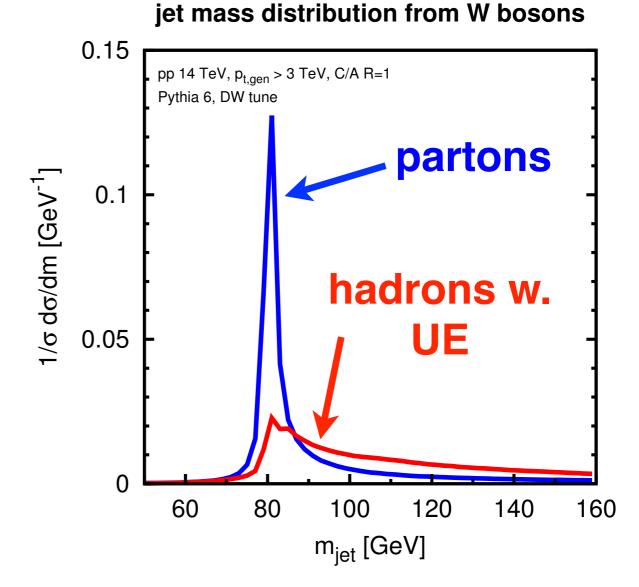

High- p_t regime: EW object X is boosted, decay is collimated, $q\bar{q}$ both in same jet

Happens for $p_t \gtrsim 2m/R$ $p_t \gtrsim 320$ GeV for $m = m_W$, R = 0.5 Most obvious way of detecting a boosted decay is through the mass of the jet

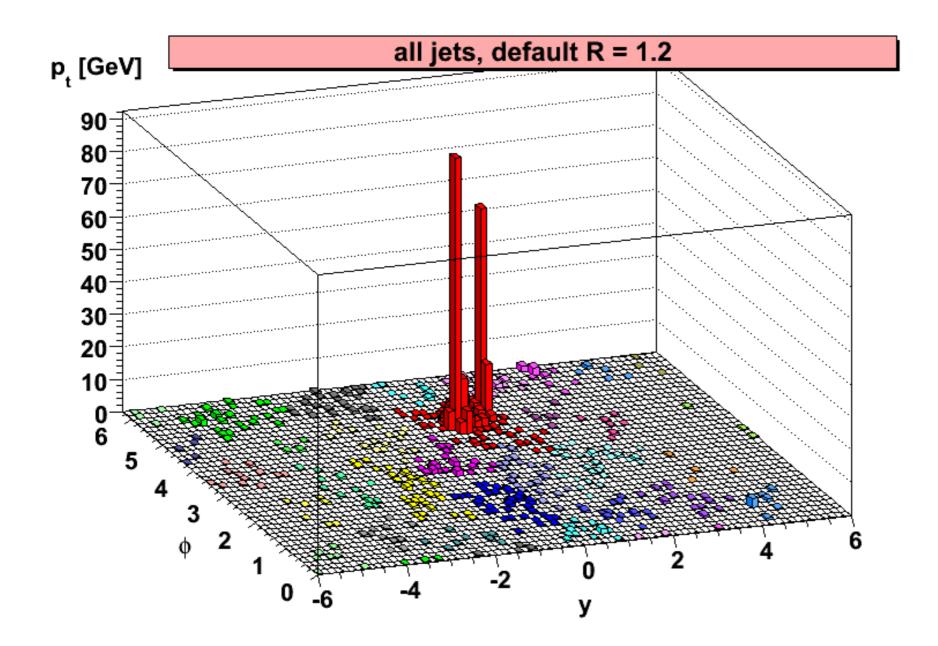

But jet mass is **poor** in practice:

e.g., narrow W resonance highly smeared by QCD radiation

(mainly underlying event/ pileup)

A range of techniques being used for varied BSM scenarios

developing an understanding – "jetography"

What do different tools do the same/differently?

Are they exploiting all relevant physics?

What methods can we reliably use to predict their behaviour?

[These tools will become ever more common at 14 TeV]

To fully understand "Boost" you want to study all possible signal (W/Z/H/top/...) and QCD jets.

But you need to start somewhere. We chose the QCD jets because:

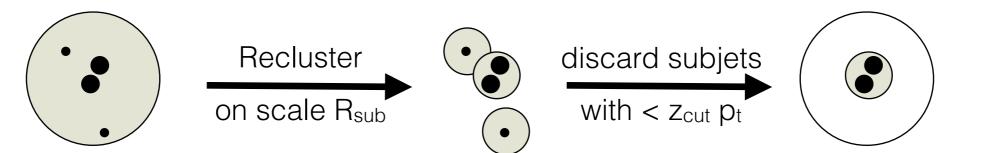

(a) they have the richest structure.

(b) once you know understand the QCD jets, the route for understanding signal jets becomes clear too.

study 3 taggers/groomers

study 3 taggers/groomers

Cannot possibly study all tools These 3 are widely used

Trimming

Mass-drop tagger (MDT, aka BDRS)

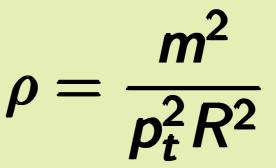

The key variables

For phenomenology

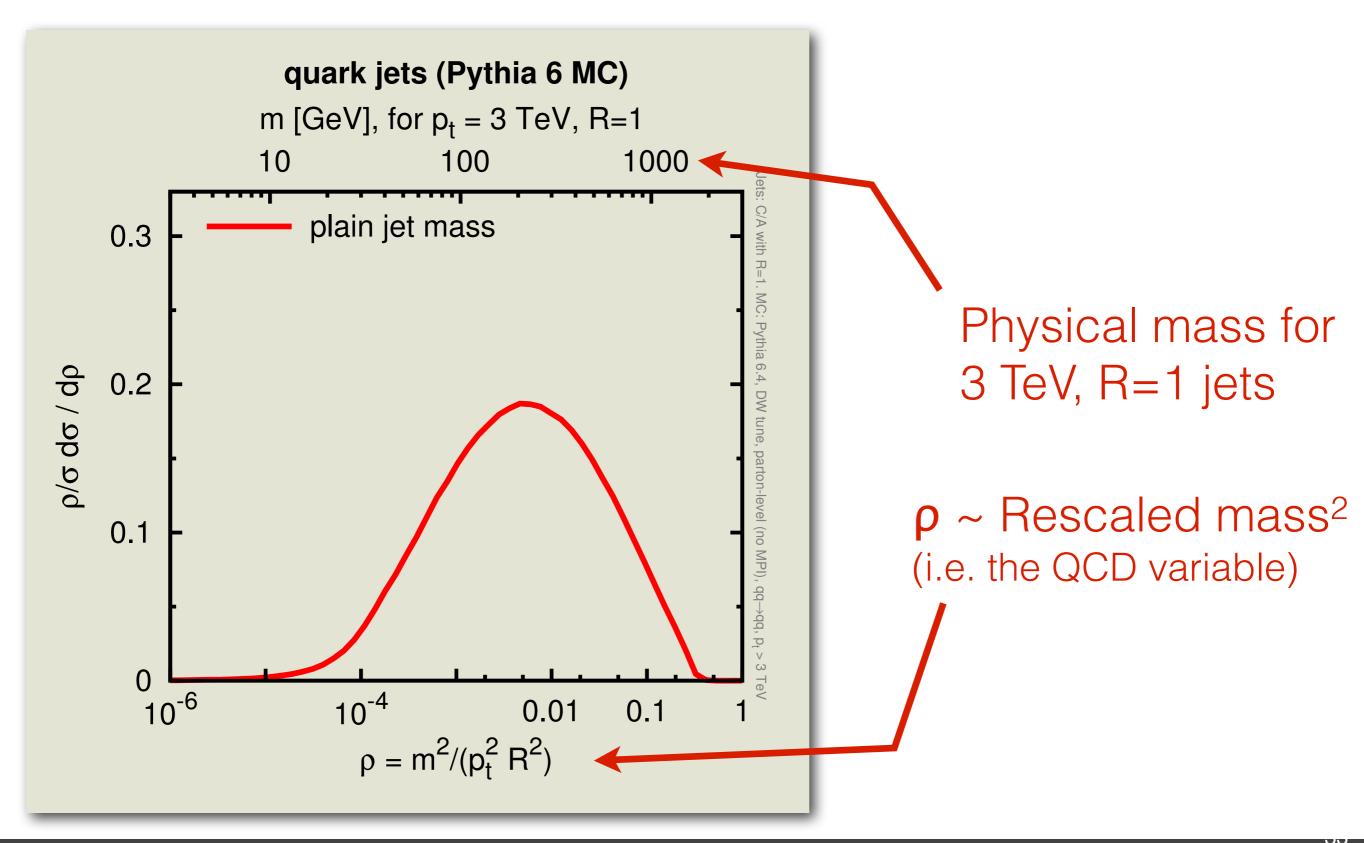

Jet mass: m

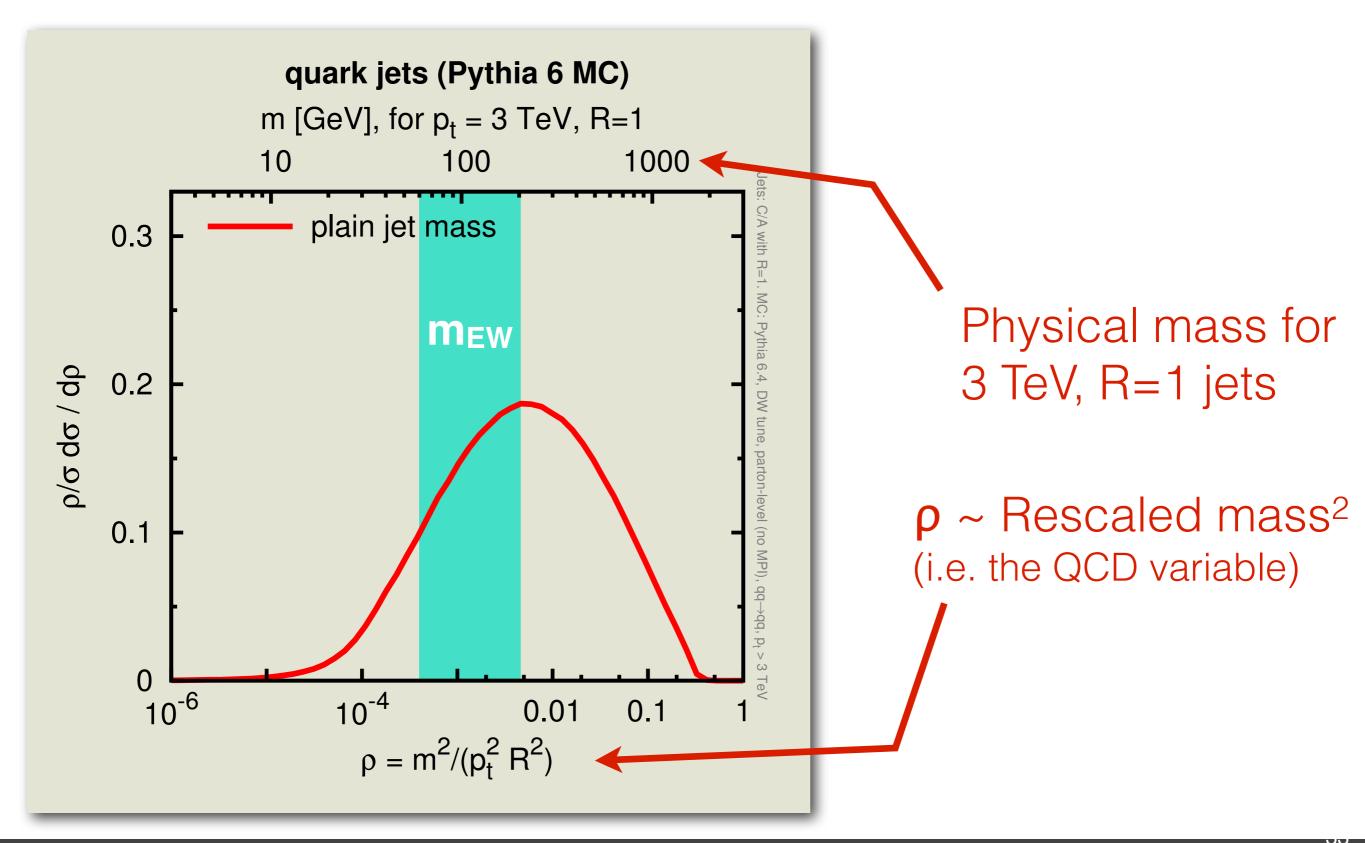

[as compared to W/Z/H or top mass] For QCD calculations

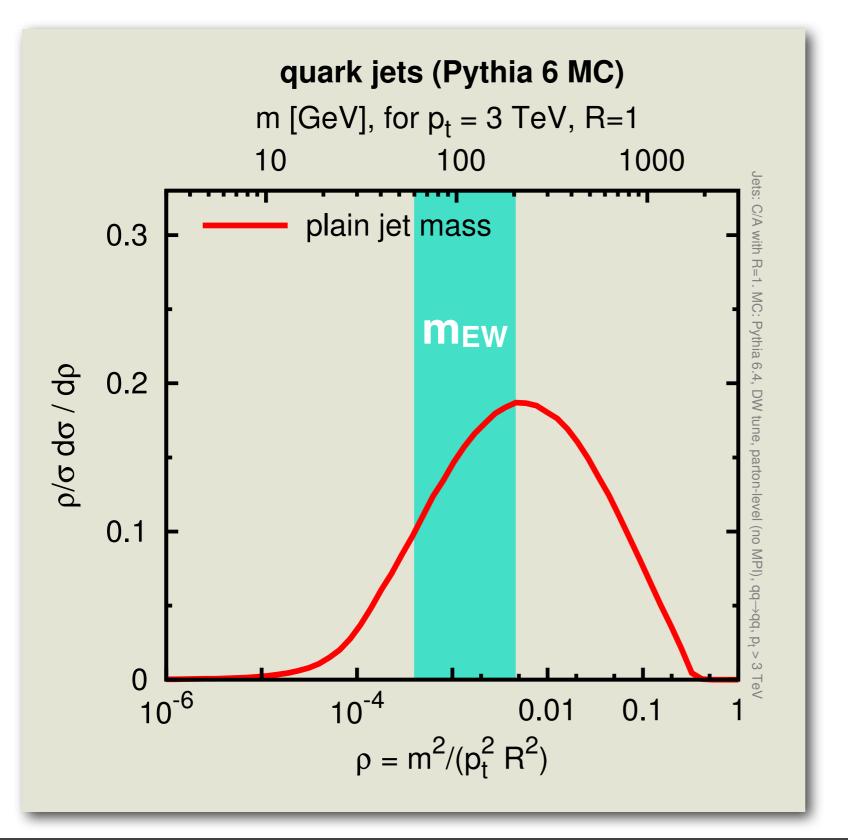

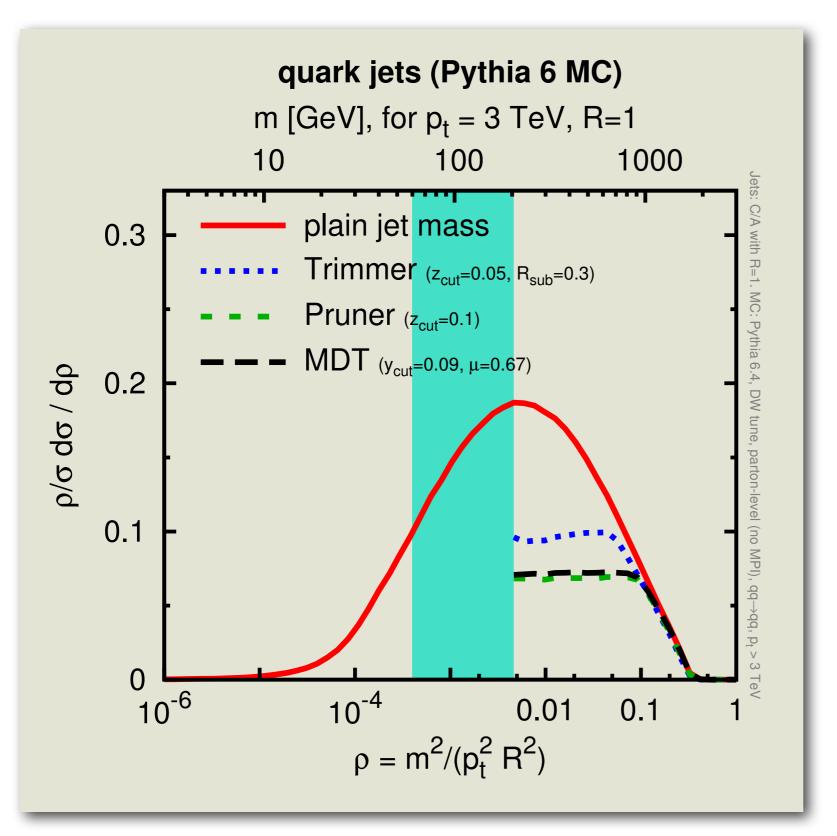

[R is jet opening angle – or radius]

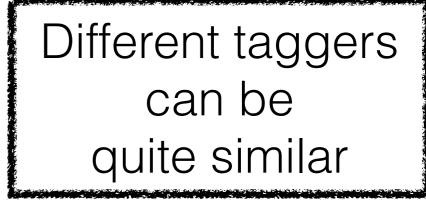

Because *p* is invariant under boosts along jet direction

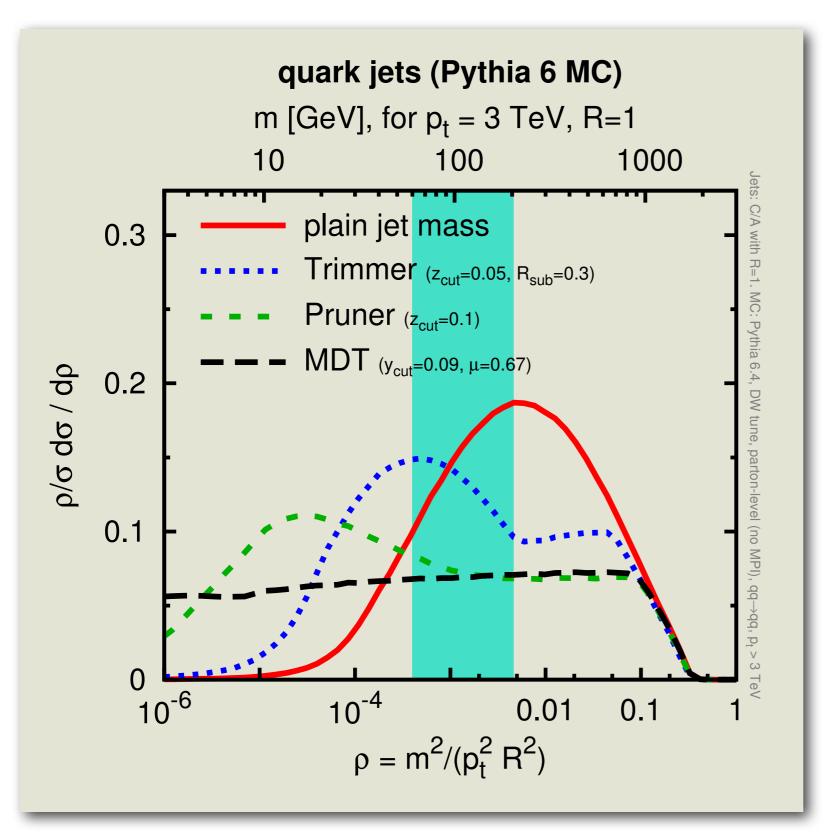

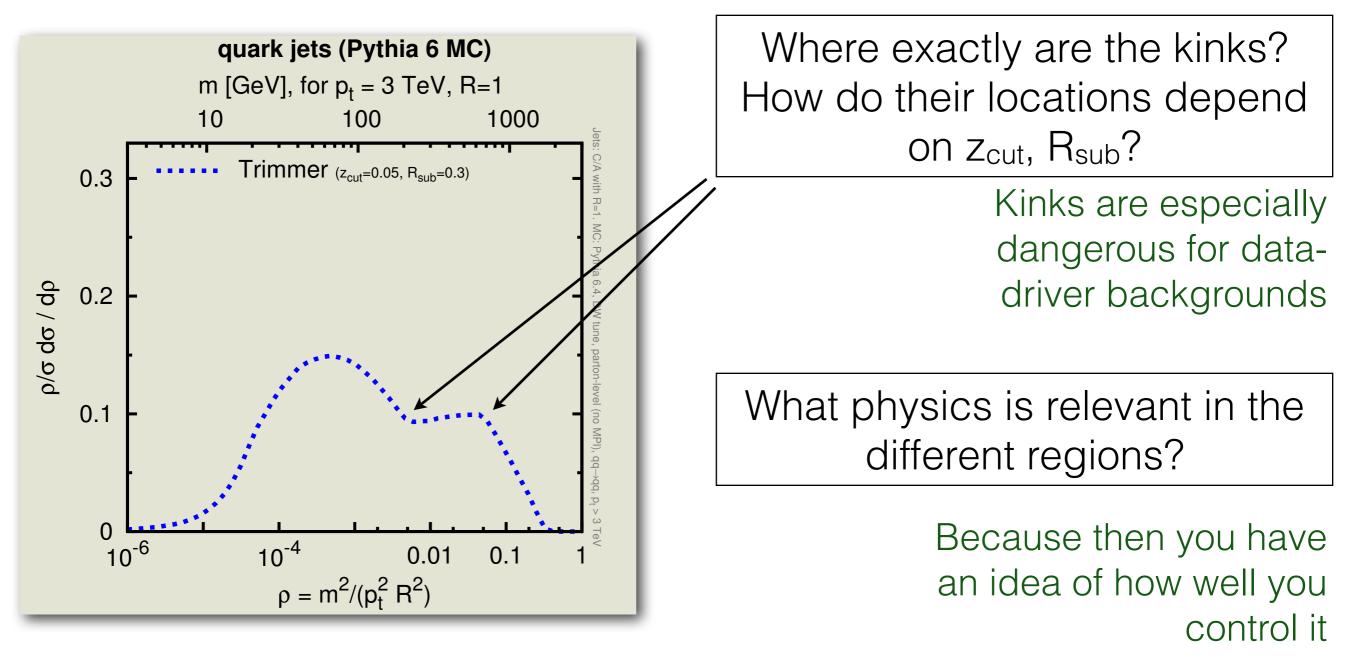

But only for a limited range of masses

What might we want to find out?

And maybe you can make better taggers

[Analytic] understanding

arXiv:1307.0007 Dasgupta, Fregoso, Marzani & GPS +Dasgupta, Fregoso, Marzani & Powling, 1307.0013

Key calculations related to plain jet mass

- Catani, Turnock, Trentadue & Webber, '91: heavy-jet mass in e+e-

- Forshaw, Seymour et al '06-'12, Catani, de Florian & Rodrigo '12: factorization breaking terms (aka super-leading logs)

Jet masses are hard! Will tagging/grooming make them impossible?

Take all particles in a jet of radius **R** and recluster them into subjets with a jet definition with radius

R_{sub} < R

The subjets that satisfy the condition

 $p_t^{(subjet)} > \mathbf{Z_{cut}} p_t^{(jet)}$

are kept and merged to form the trimmed jet.

Trimming Krohn, Thaler & Wang '09

two parameters: R_{sub} and z_{cut}

Use z_{cut} because signals (bkgds) tend to have large (small) z_{cut}

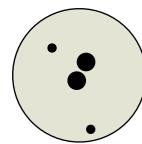

Take all particles in a jet of radius **R** and recluster them into subjets with a jet definition with radius

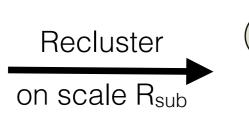

R_{sub} < R

The subjets that satisfy the condition

 $p_t^{(subjet)} > \mathbf{Z_{cut}} p_t^{(jet)}$

are kept and merged to form the trimmed jet.

Our approximations

- $\rho \ll 1$ logs of ρ get resummed
- pretend $R \ll 1$

• $Z_{cut} \ll 1$, but (log Z_{cut}) not large

These approximations are not as "wild" as they might sound.

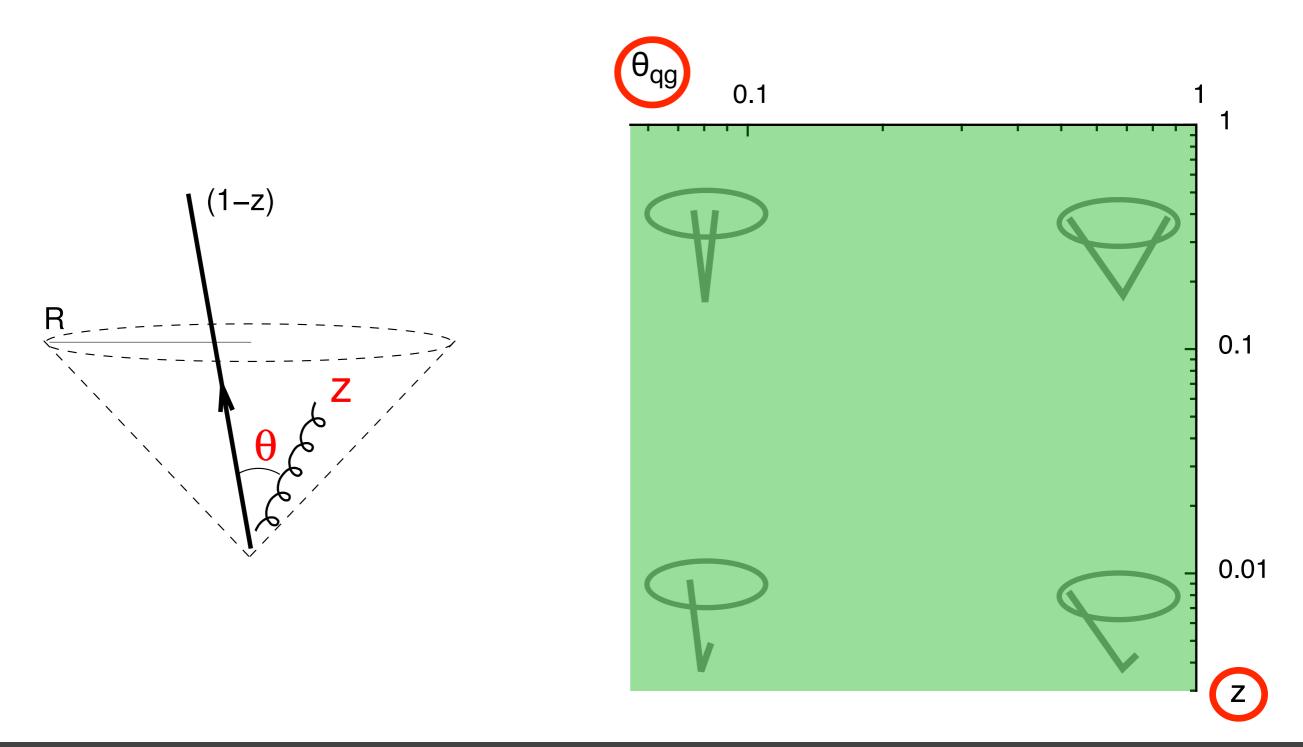

They can also be relaxed.

But our aim for now is to understand the taggers — we

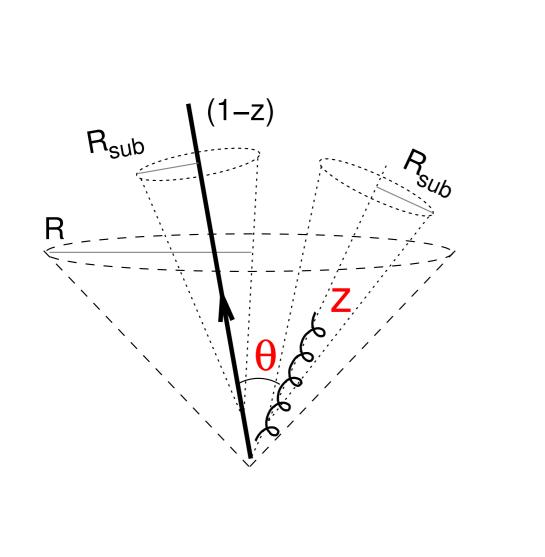

Leading Order — 2-body kinematic plane

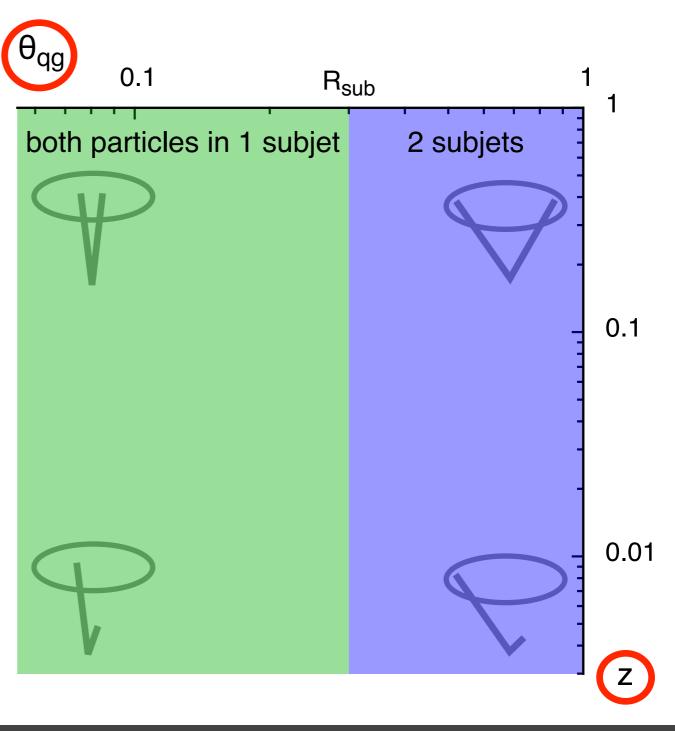

At $O(\alpha_s)$, a quark jet emits a gluon. We study this as a function of the gluon momentum fraction z and the quark-gluon opening angle θ

Leading Order — 2-body kinematic plane

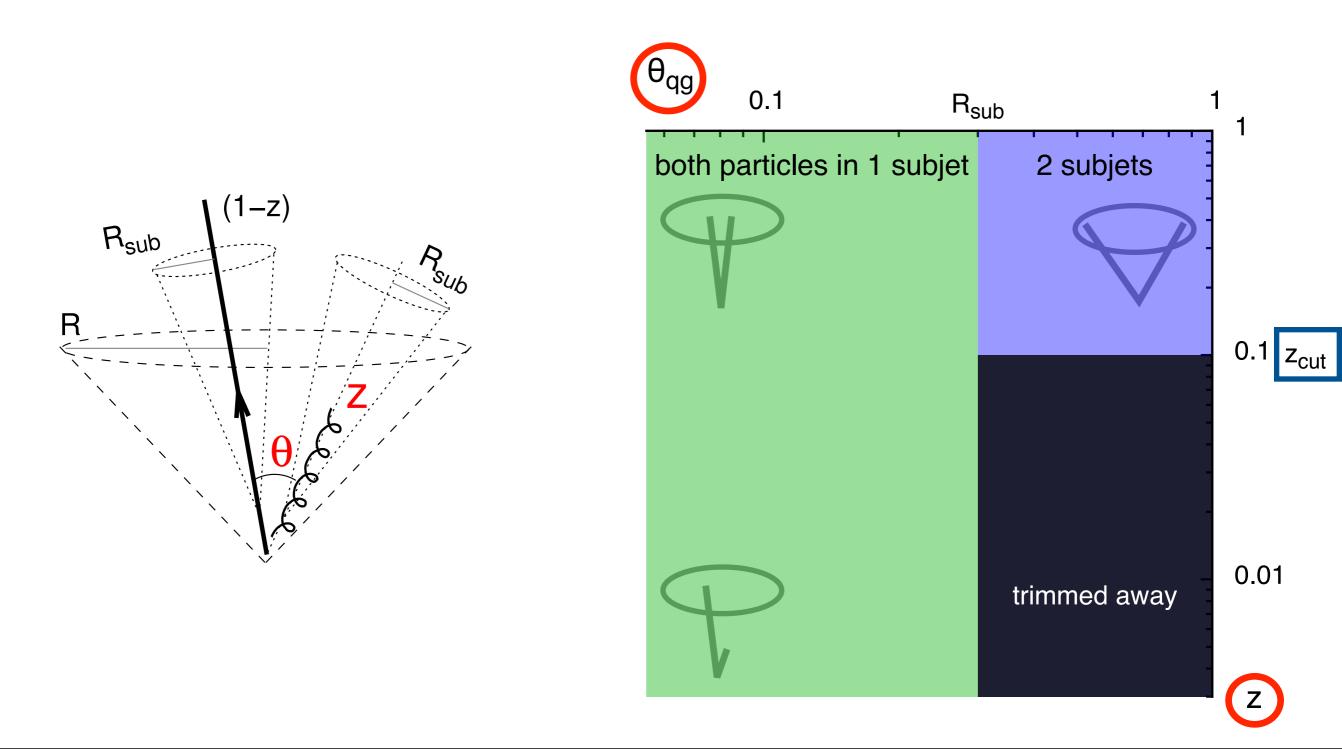

At O(α_s), a quark jet emits a gluon. We study this as a function of the gluon momentum fraction z and the quark-gluon opening angle θ

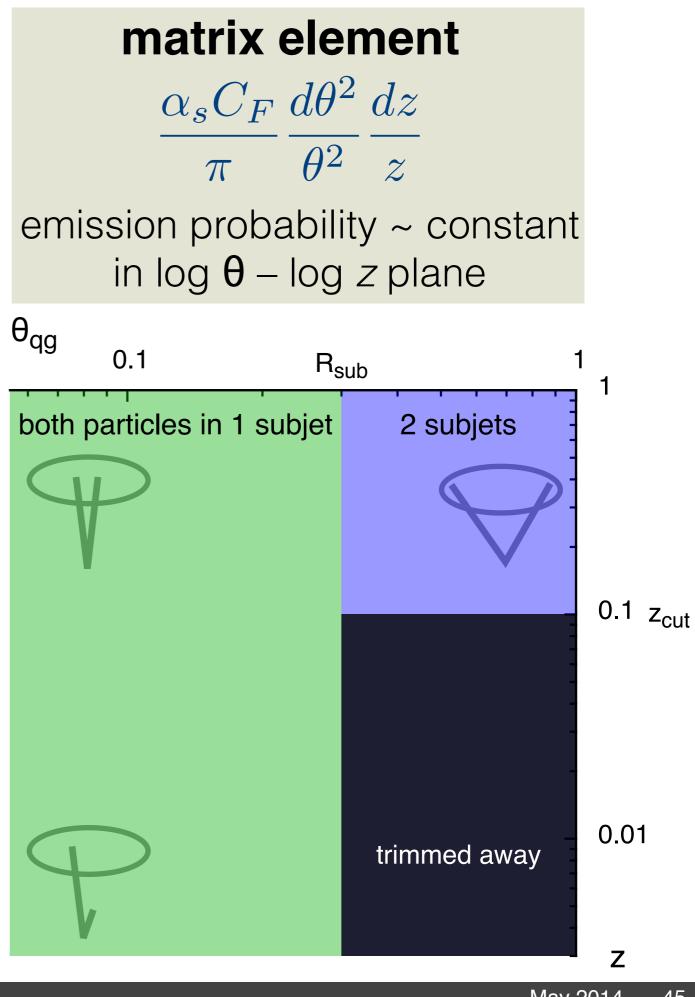

Leading Order — 2-body kinematic plane

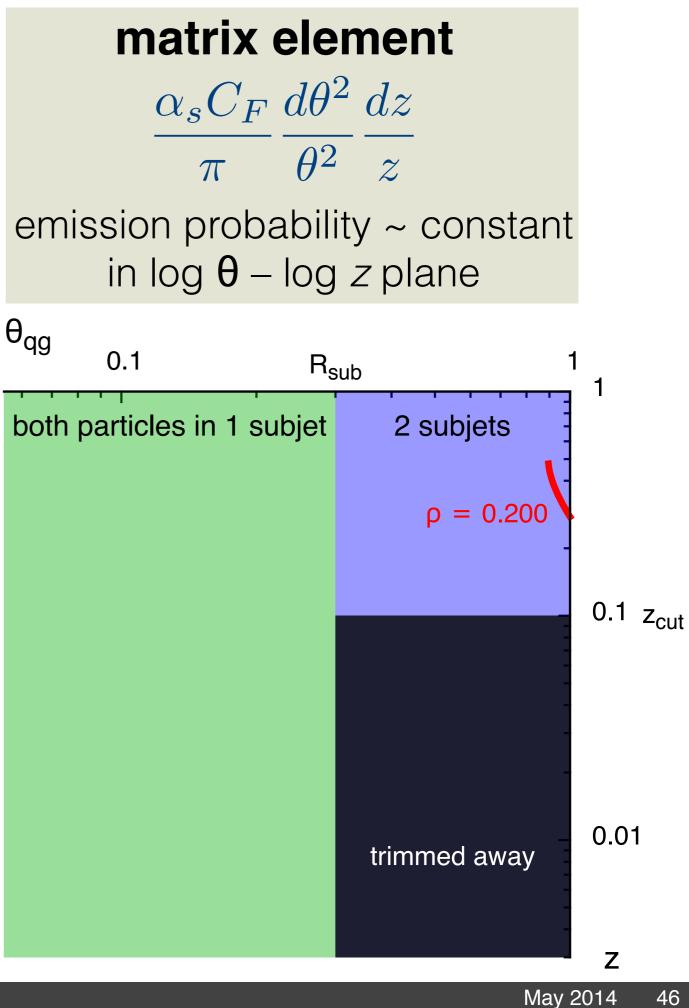

At $O(\alpha_s)$, a quark jet emits a gluon. We study this as a function of the gluon momentum fraction z and the quark-gluon opening angle θ

jet mass

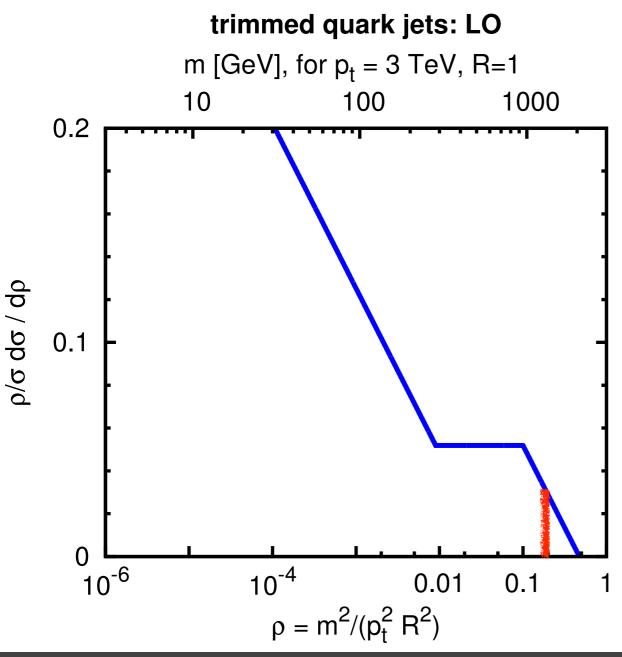

$$\rho = z(1-z)\theta^2$$

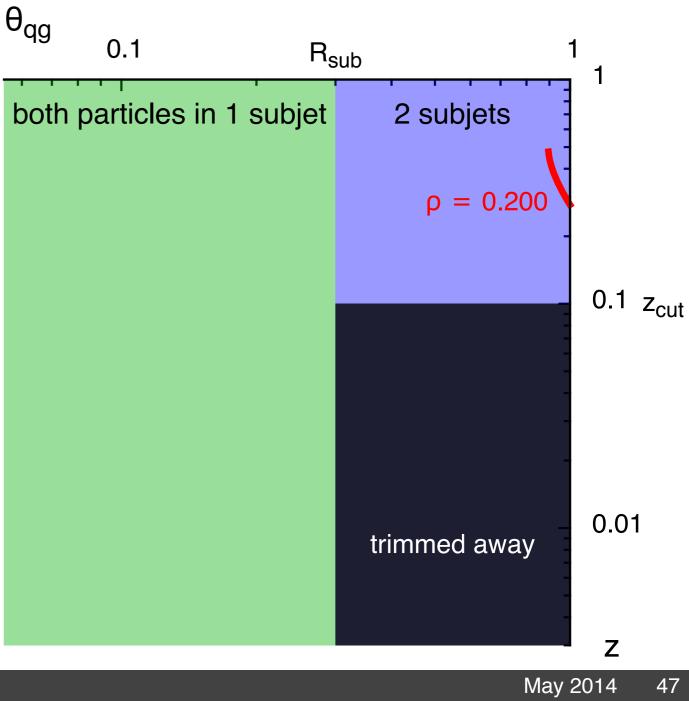

$$\rho = z(1-z)\theta^2$$

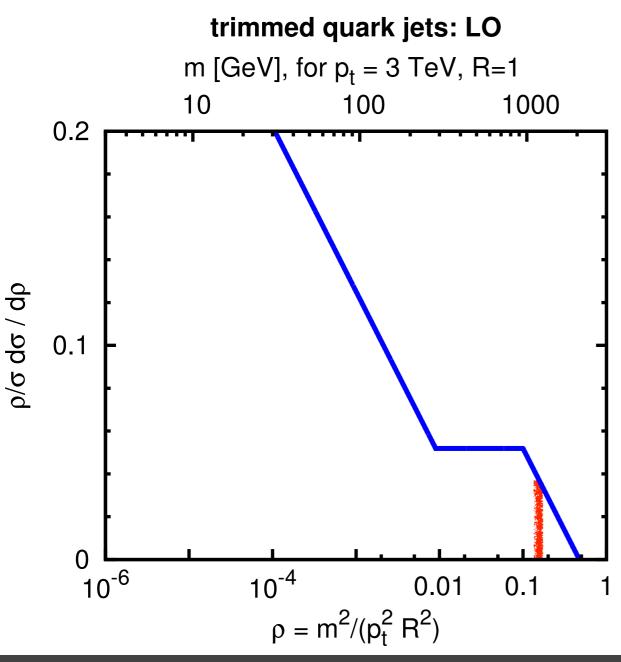

LO differential cross section

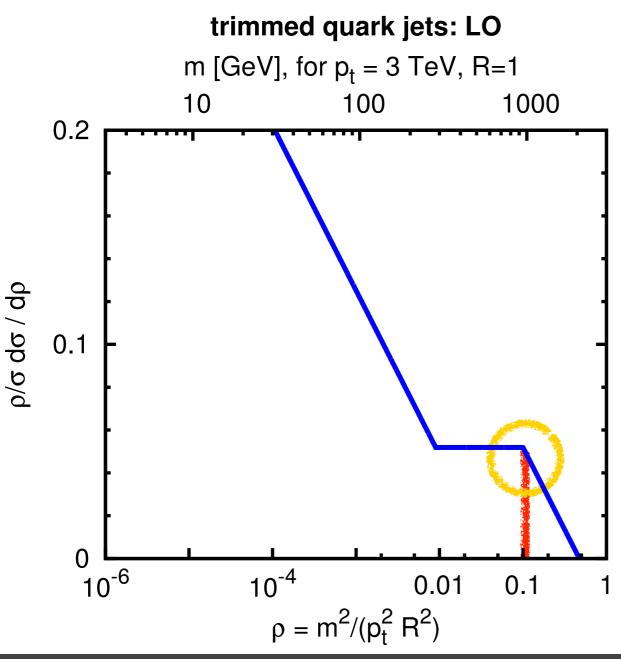

$$\rho = z(1-z)\theta^2$$

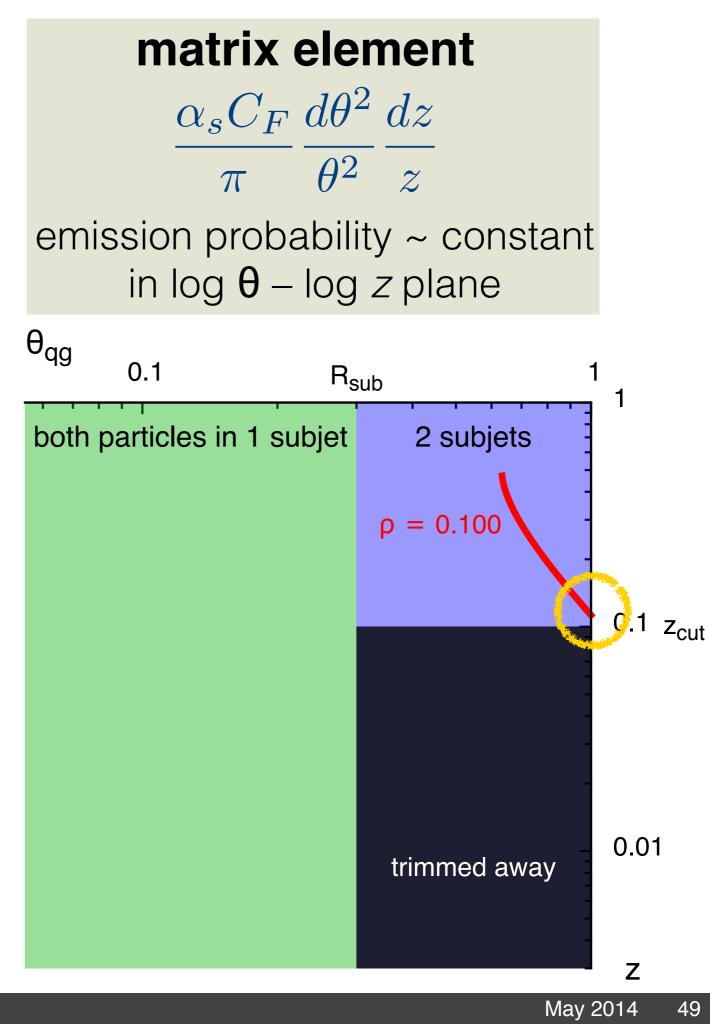

matrix element $\alpha_s C_F \ d\theta^2 \ dz$ $\pi \frac{\theta^2}{\theta^2}$ emission probability ~ constant in $\log \theta - \log z$ plane θ_{qg} 0.1 R_{sub} both particles in 1 subjet 2 subjets $\rho = 0.150$ 0.1 z_{cut} 0.01 trimmed away Ζ

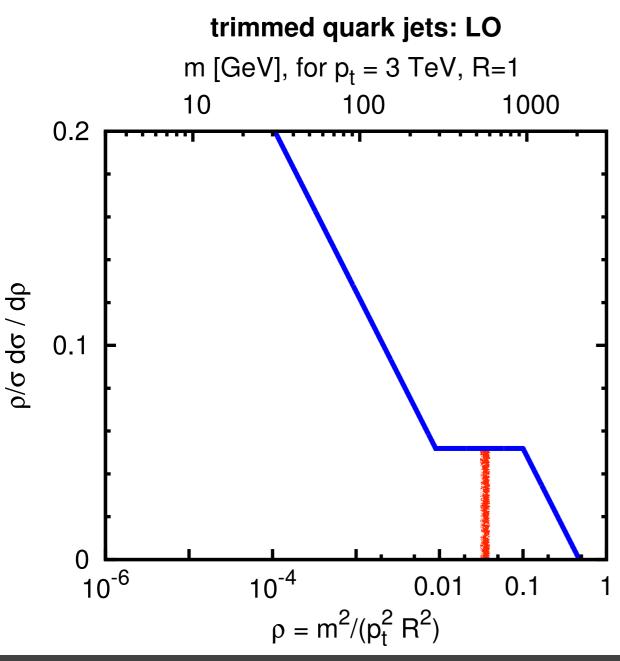

$$\rho = z(1-z)\theta^2$$

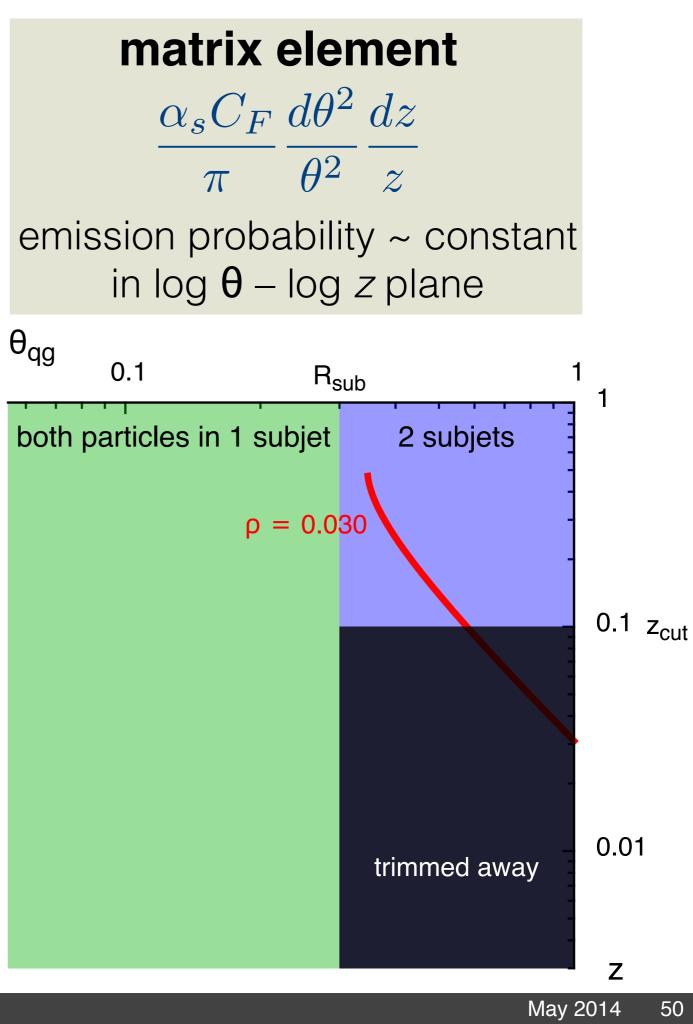

$$\rho = z(1-z)\theta^2$$

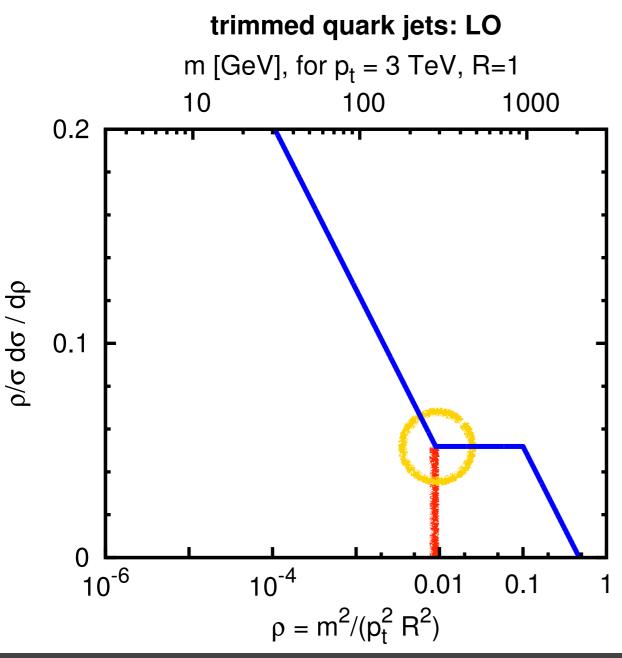

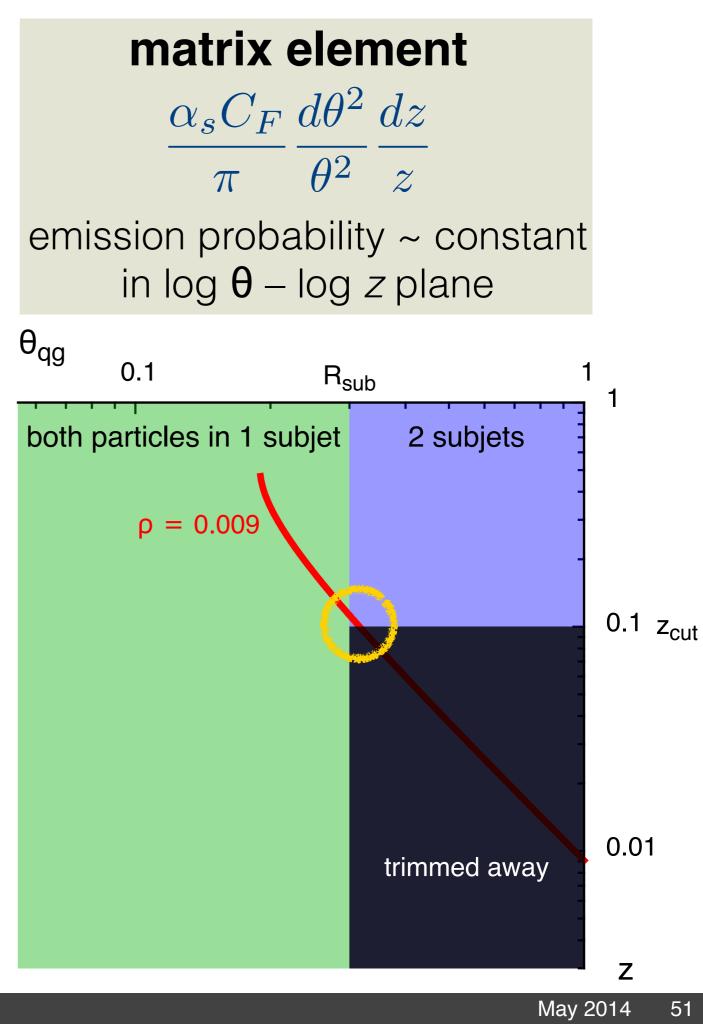

Jet Substructure

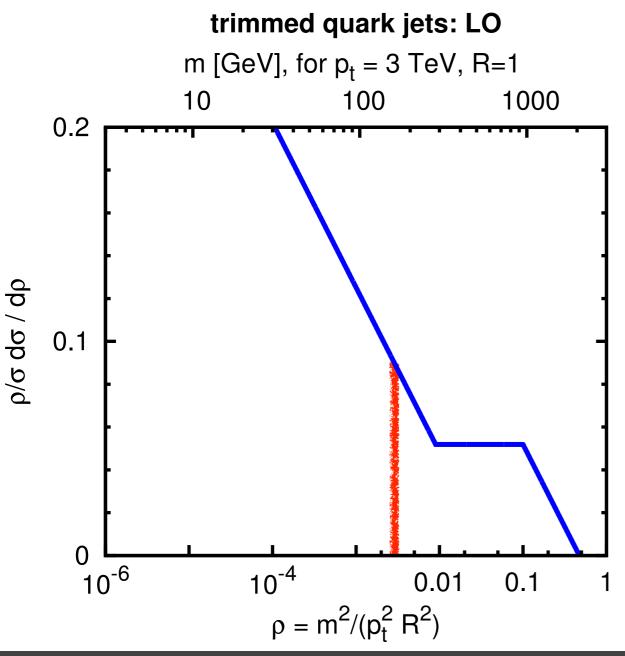

$$\rho = z(1-z)\theta^2$$

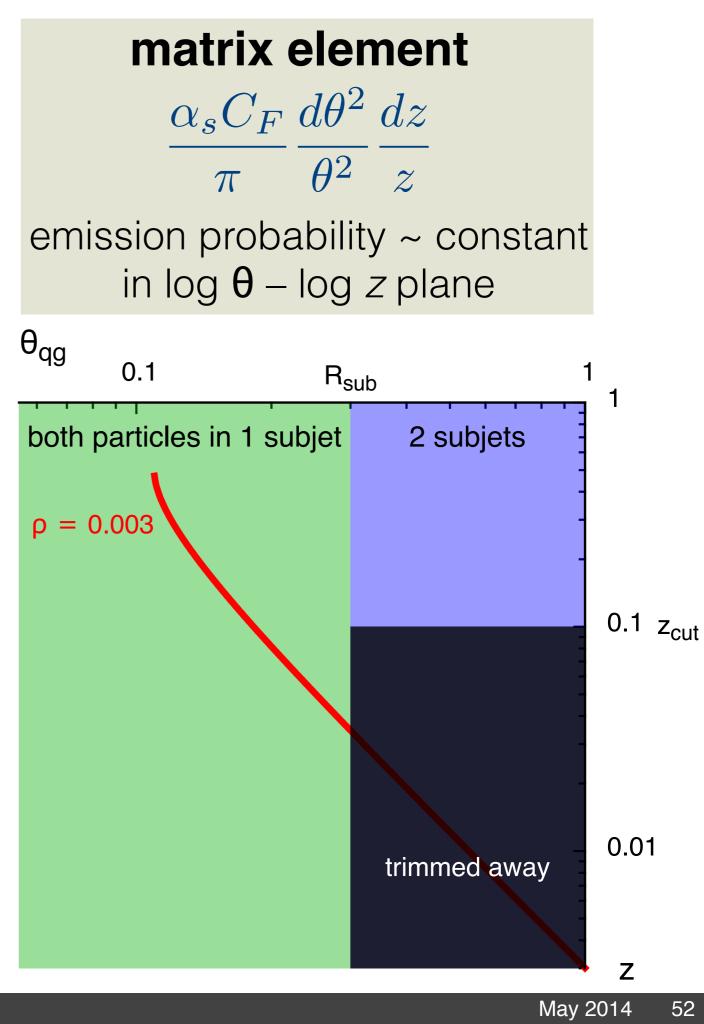

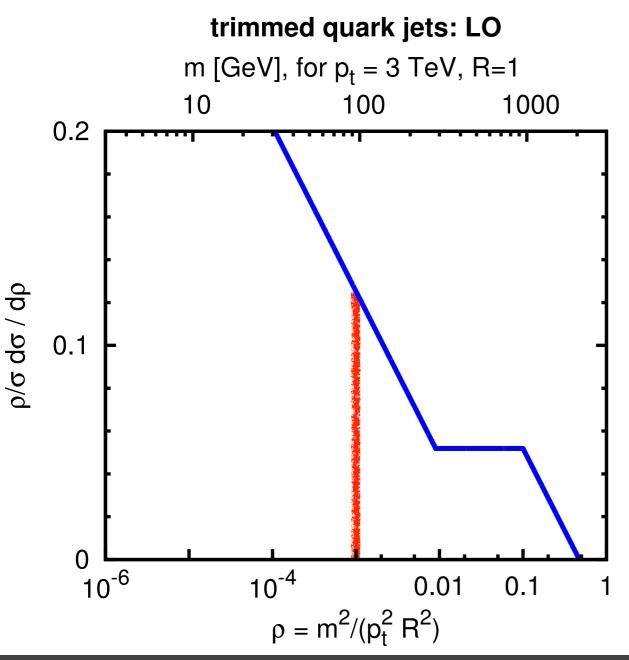

$$\rho = z(1-z)\theta^2$$

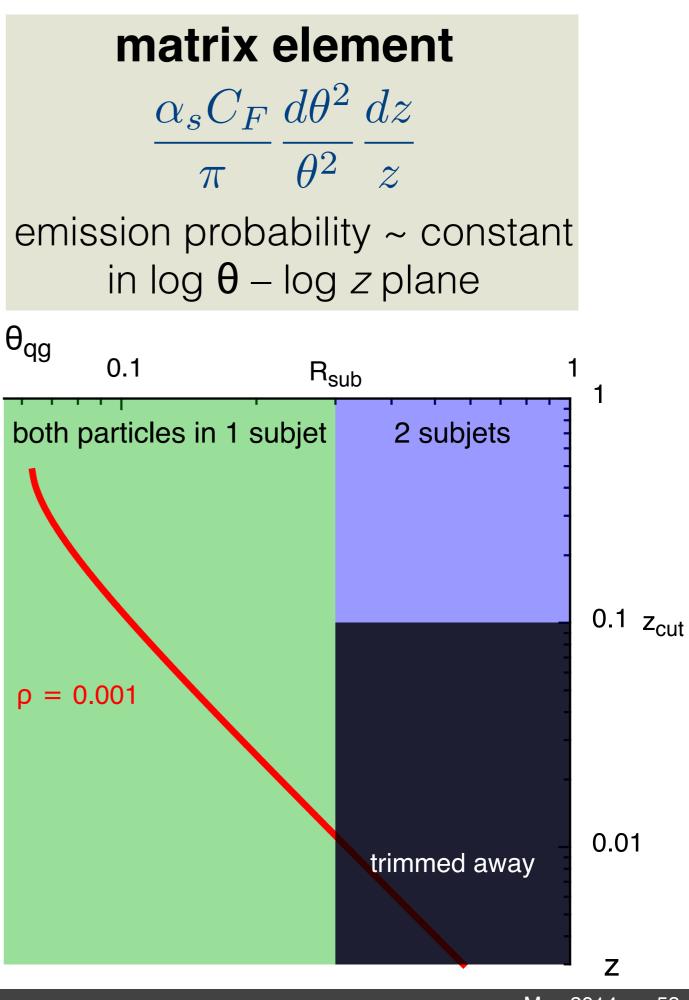

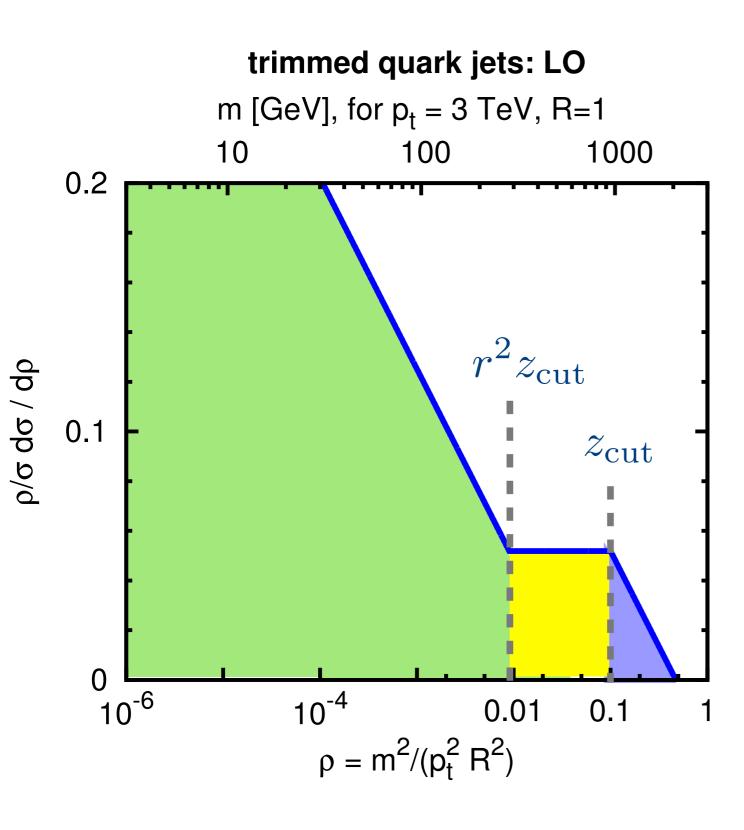

$$\rho = z(1-z)\theta^2$$

Trimming at LO in α_s

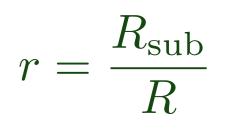

$$\frac{\rho}{\sigma} \frac{d\sigma^{(\text{trim,LO})}}{d\rho} =$$

$$\frac{\alpha_s C_F}{\pi} \left(\ln \frac{r^2}{\rho} - \frac{3}{4} \right)$$

$$\frac{\alpha_s C_F}{\pi} \left(\ln \frac{1}{z_{\rm cut}} - \frac{3}{4} \right)$$

$$\frac{\alpha_s C_F}{\pi} \left(\ln \frac{1}{\rho} - \frac{3}{4} \right)$$

continue with all-order resummation of terms $\alpha_s^n \ln^m \rho$

Inputs

QCD pattern of multiple soft/collinear emission

Analysis of taggers' behaviour for 1, 2, 3, ... n, emissions Establish which simplifying approximations to use for tagger & matrix elements

\rightarrow all orders in α_s

Output

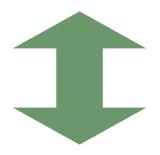

approx. formula for tagger's mass distribution for $\rho \ll 1$ $\frac{\rho}{\sigma}\frac{d\sigma}{d\rho} =$ ∞ $\sum c_{nm} \alpha_s^n \ln^m \rho$ n=1

keeping only terms with largest powers of ln ρ , e.g. m = 2n, 2n-1

Trimming

$$\rho^{\text{trim}}(k_1, k_2, \dots k_n) \simeq \sum_{i}^{n} \rho^{\text{trim}}(k_i)$$
$$\sim \max_{i} \{\rho^{\text{trim}}(k_i)\}$$

Trimmed jet reduces (~) to sum of trimmed emissions

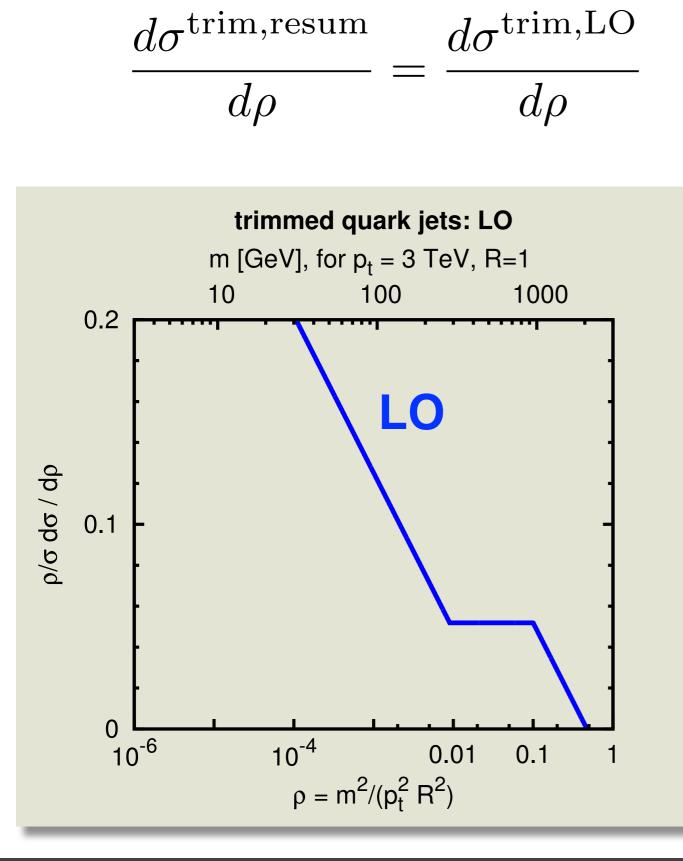

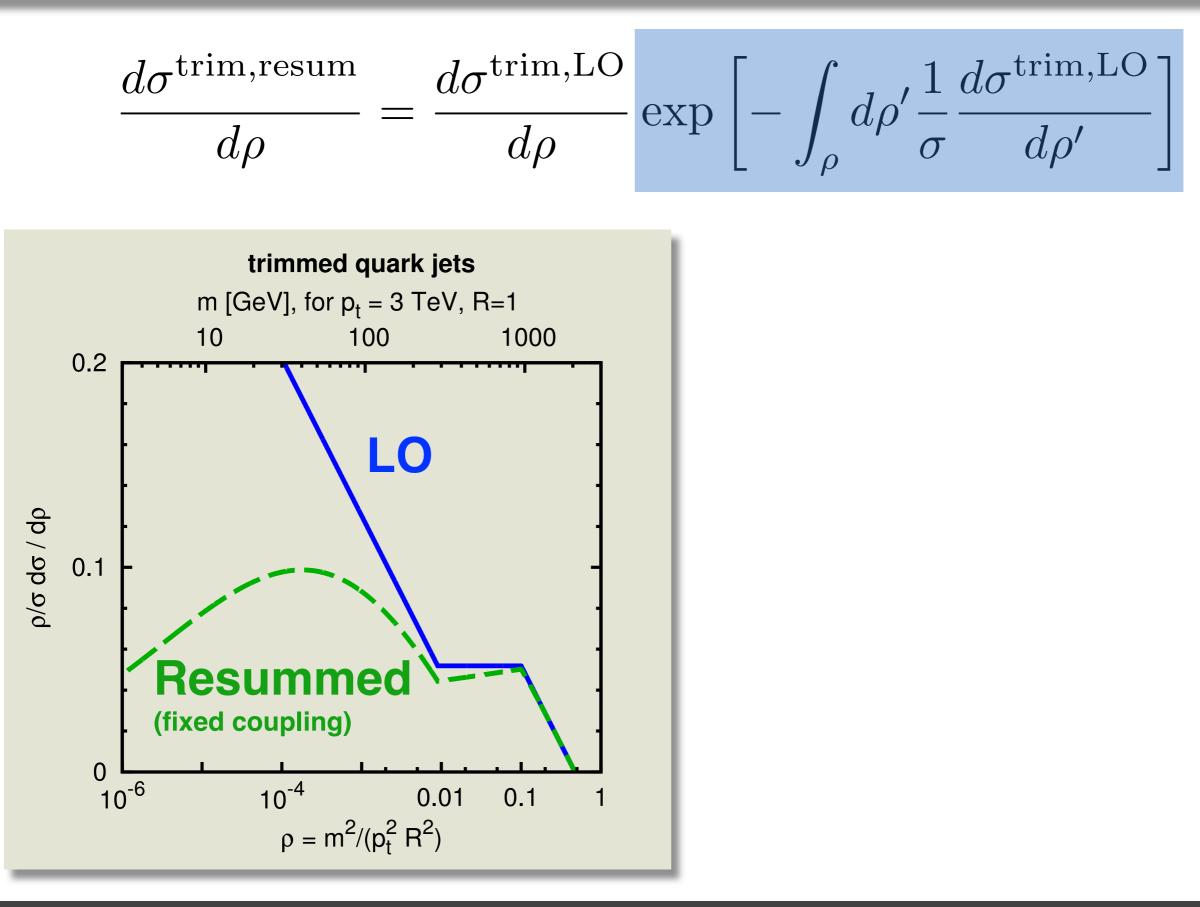

Matrix element

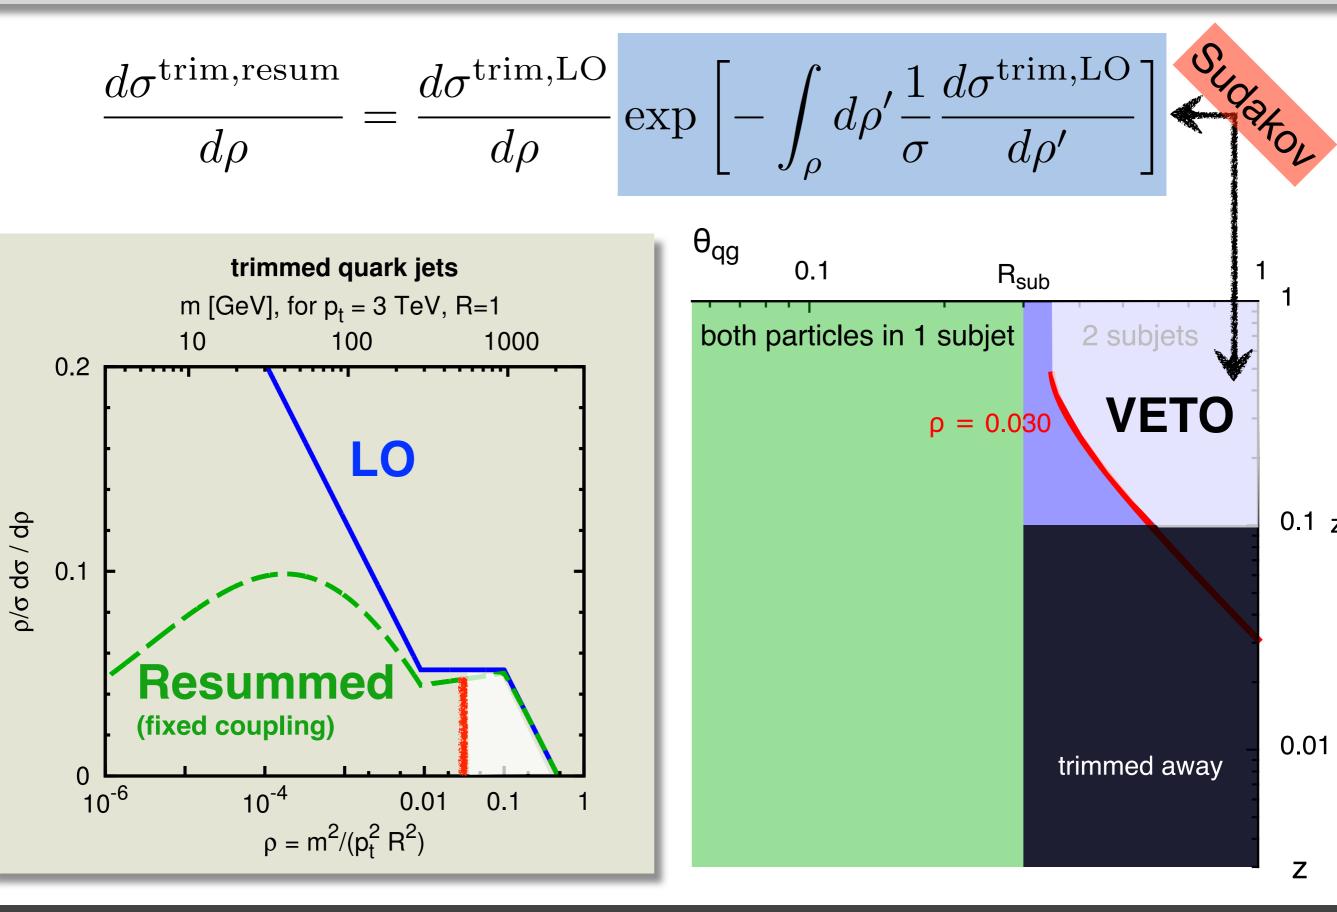

$$\sum_{n} \frac{1}{n!} \prod_{i}^{n} \frac{d\theta_{i}^{2}}{\theta_{i}^{2}} \frac{dz_{i}}{z_{i}} \frac{\alpha_{s}(\theta_{i} z_{i} p_{t}^{\text{jet}}) C_{F}}{\pi}$$

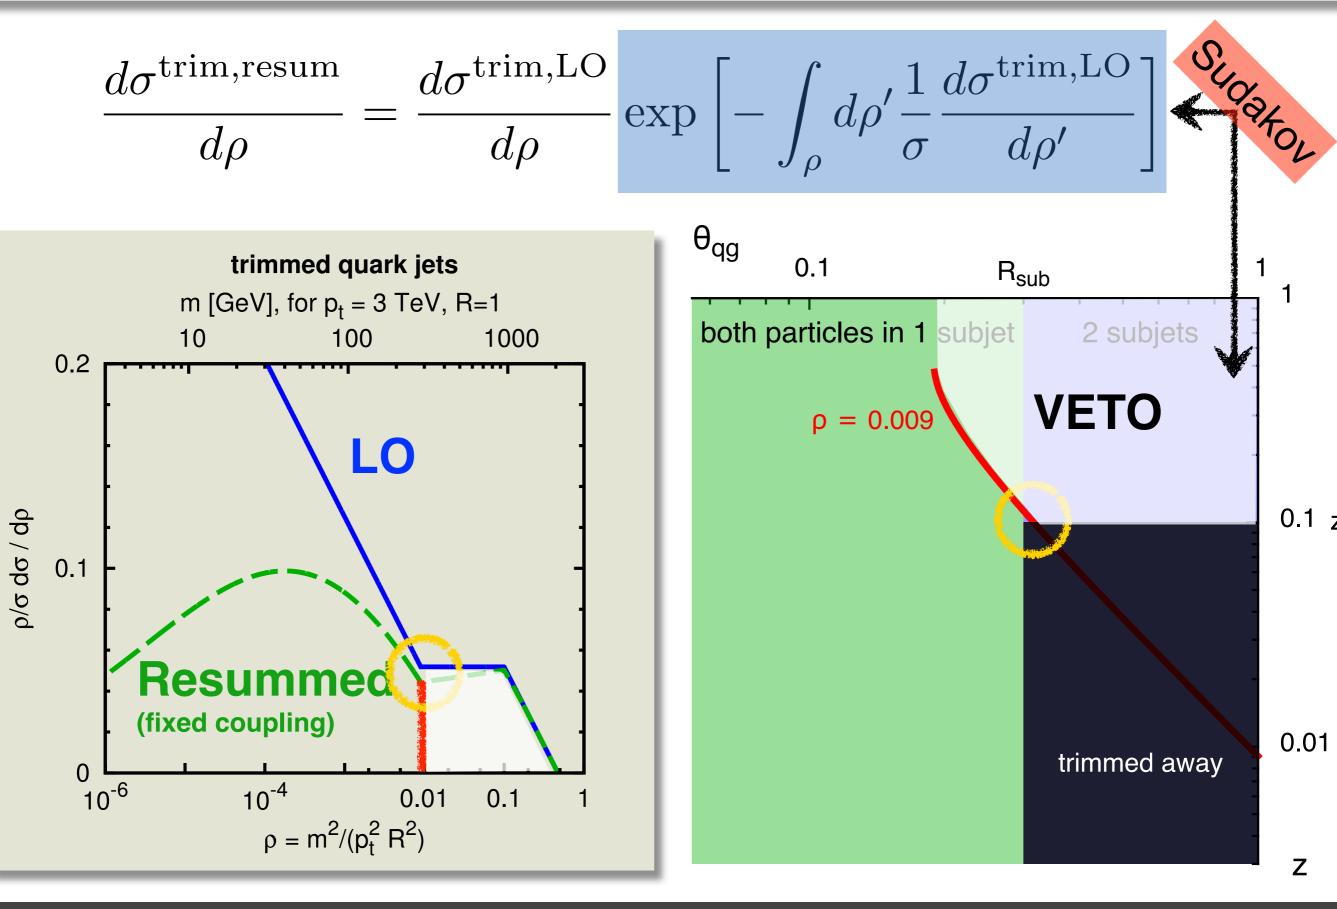

can use QED-like independent emissions, as if gluons don't split

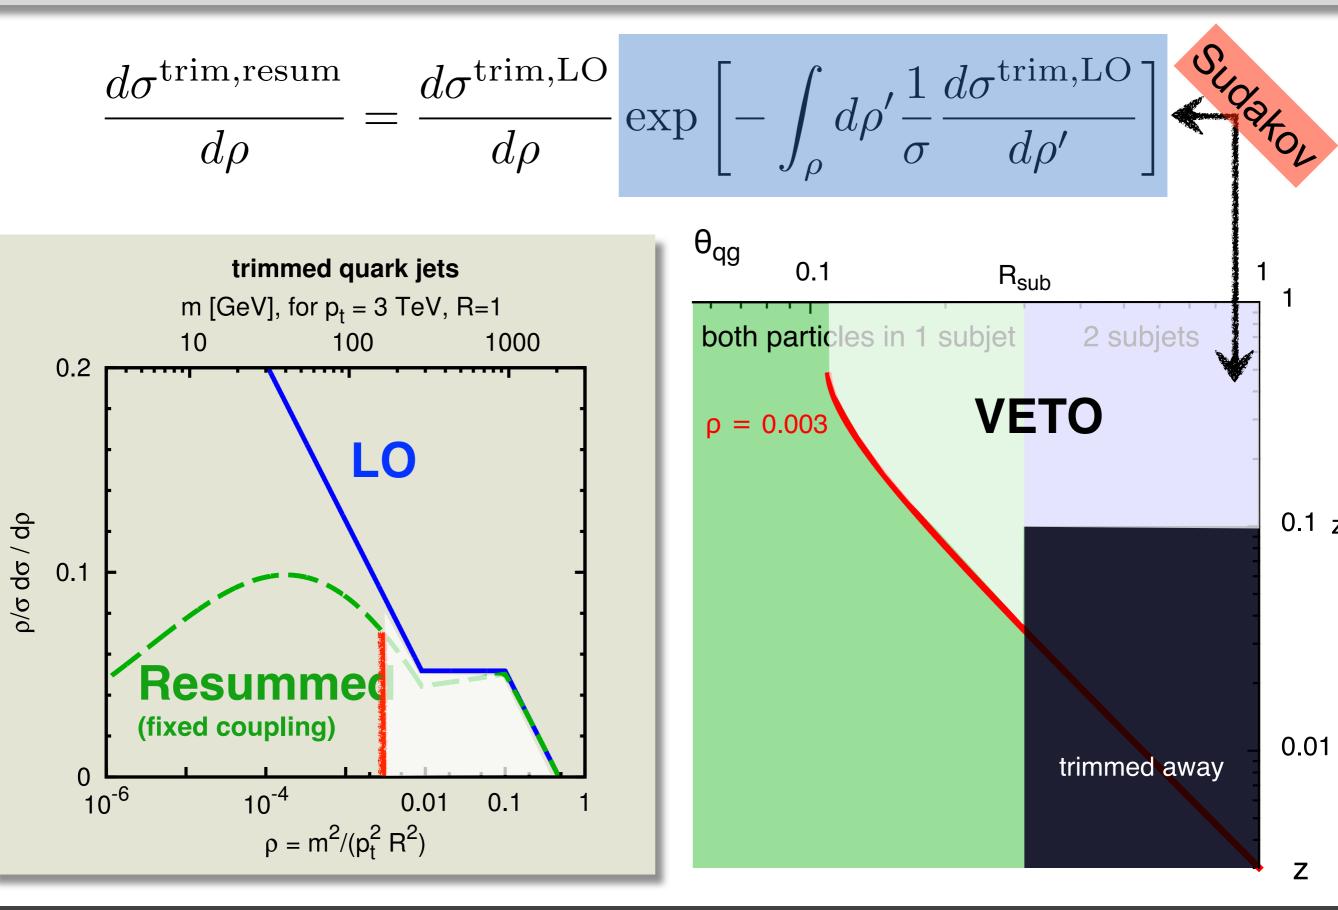

+ virtual corrections, essentially from unitarity

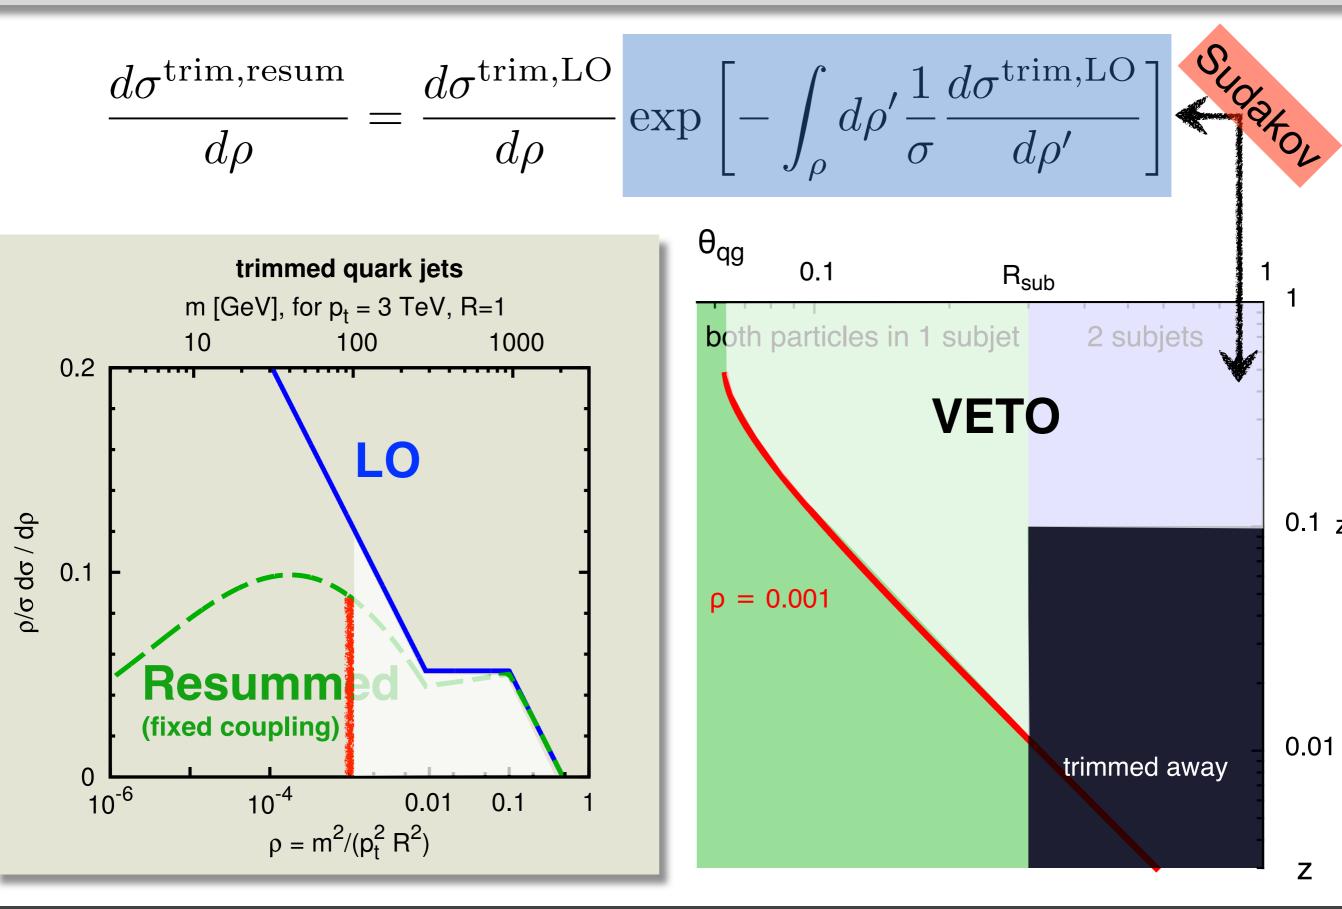

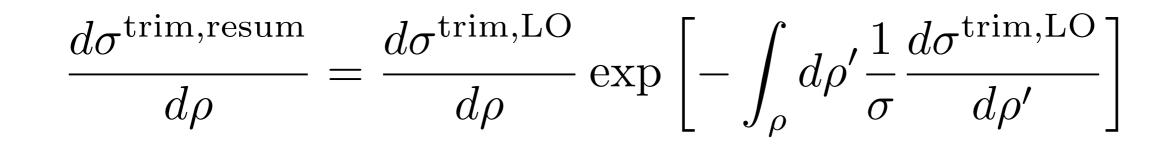

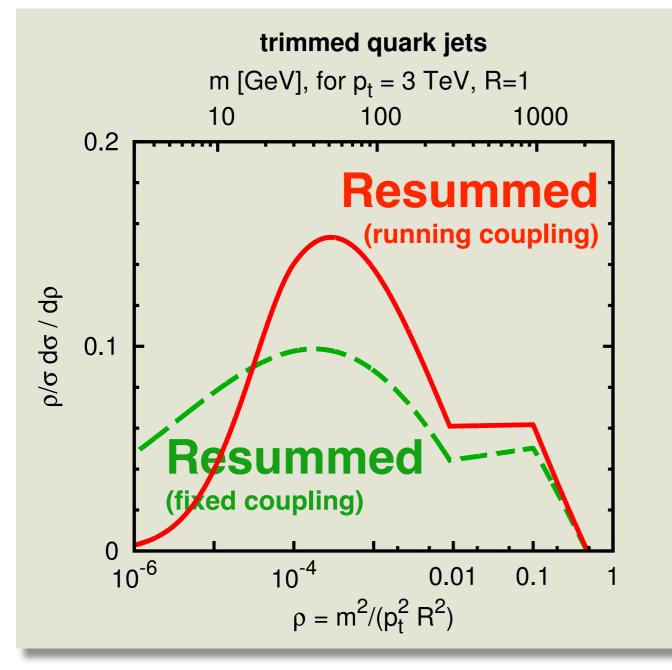

Trimming at all orders

Trimming at all orders

Full resummation also needs treatment of running coupling

What logs, what accuracy?

Express accuracy for "cumulative distⁿ" $\Sigma(\rho)$:

$$\Sigma(\rho) = \int_0^{\rho} d\rho' \frac{1}{\sigma} \frac{d\sigma}{d\rho'}$$

Use shorthand L = log $1/\rho$

Trimming's **leading logs** (LL, in Σ) are:

$$\alpha_s L^2, \, \alpha_s^2 L^4, \, \dots \, \text{I.e.} \, \boldsymbol{\alpha_s^n L^{2n}}$$

Just like the jet mass

We also have **next-to-leading logs** (NLL): $\alpha_s^n L^{2n-1}$

What logs, what accuracy?

Express accuracy for "cumulative distⁿ" $\Sigma(\rho)$:

$$\Sigma(\rho) = \int_0^{\rho} d\rho' \frac{1}{\sigma} \frac{d\sigma}{d\rho'}$$

Use shorthand L = log $1/\rho$

Trimming's **leading logs** (LL, in Σ) are:

$$\alpha_s L^2, \, \alpha_s^2 L^4, \, \dots \, \text{I.e.} \, \boldsymbol{\alpha_s^n L^{2n}}$$

Just like the jet mass

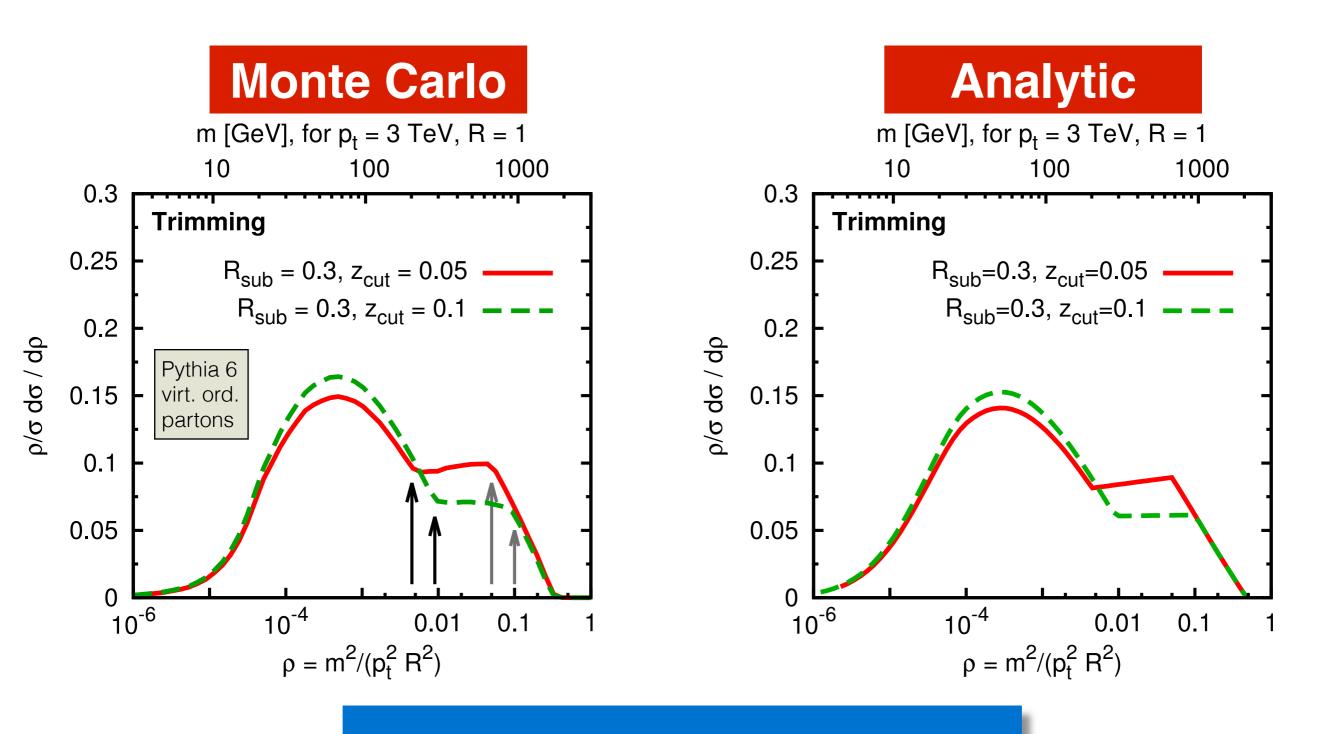

We also have **next-to-leading logs** (NLL): $\alpha_s^n L^{2n-1}$

Could we do better? Yes: NLL in In Σ :

 $\ln \Sigma: \alpha_s^n L^{n+1} \text{ and } \alpha_s^n L^n$

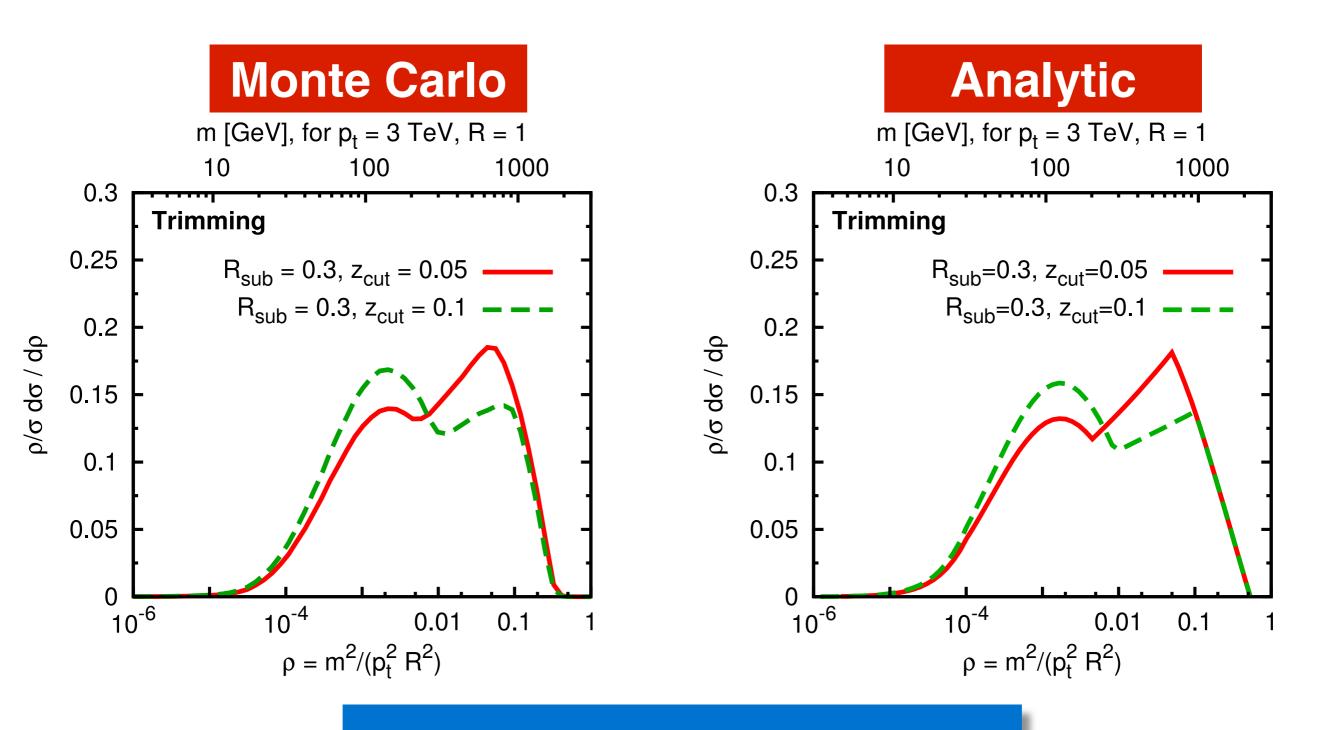

Trimmed mass is like plain jet mass (with $R \rightarrow R_{sub}$), and this accuracy involves **non-global logs**, **clustering logs**

Trimming: MC v. analytics

Non-trivial agreement! (also for dependence on parameters)

Trimming: MC v. analytics

Non-trivial agreement! (also for dependence on parameters)

For a jet clustered with C/A:

- 1. undo last clustering step to break jet (mass m) into two subjets with $m_1 > m_2$
- 2. If significant mass-drop ($m_1 < \mu m$) and subjet energy-sharing not too asymmetric $\min(p_{t1}^2, p_{t2}^2)\Delta R_{12}^2 < y_{\rm cut}m^2$

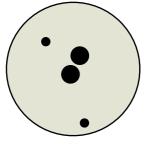

jet is tagged.

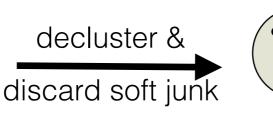

3. Otherwise discard subjet 2, and go to step 1 with jet \rightarrow subjet 1.

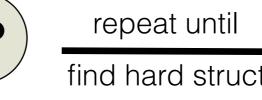

Mass-Drop Tagger

Butterworth, Davison, Rubin & GPS '08

two parameters: µ and y_{cut} (~ z_{cut})

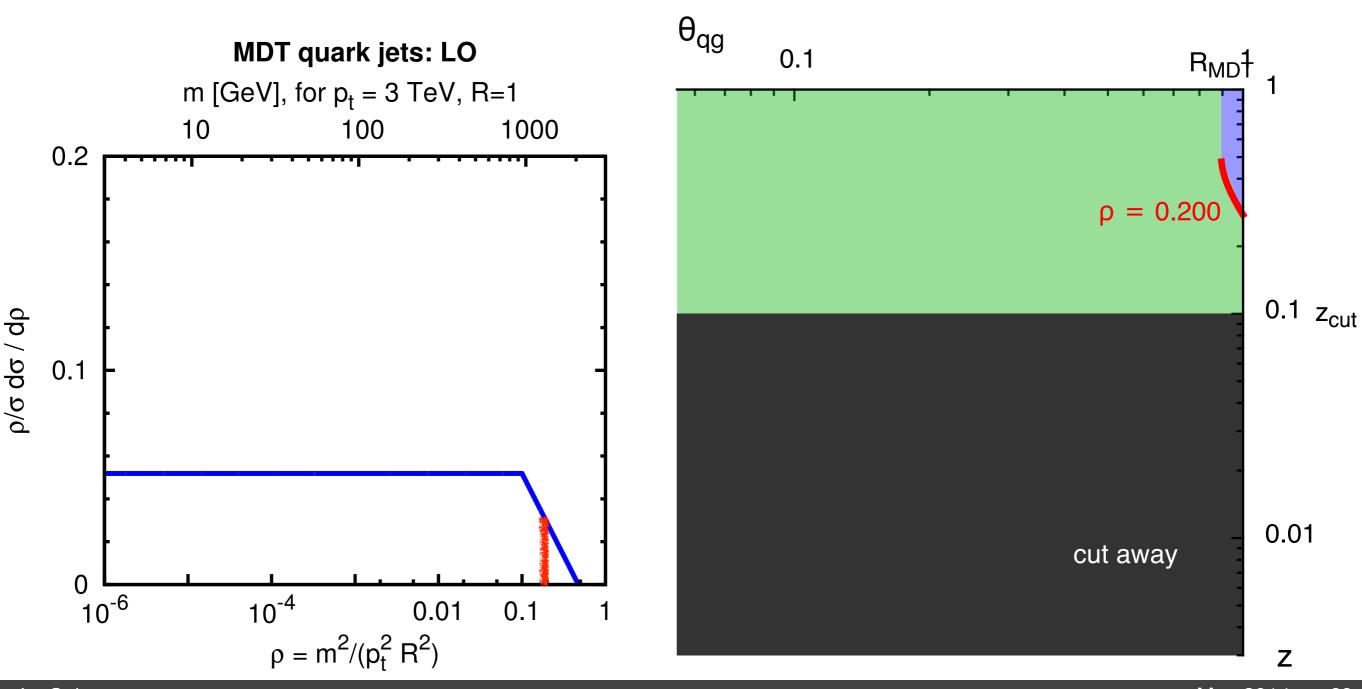

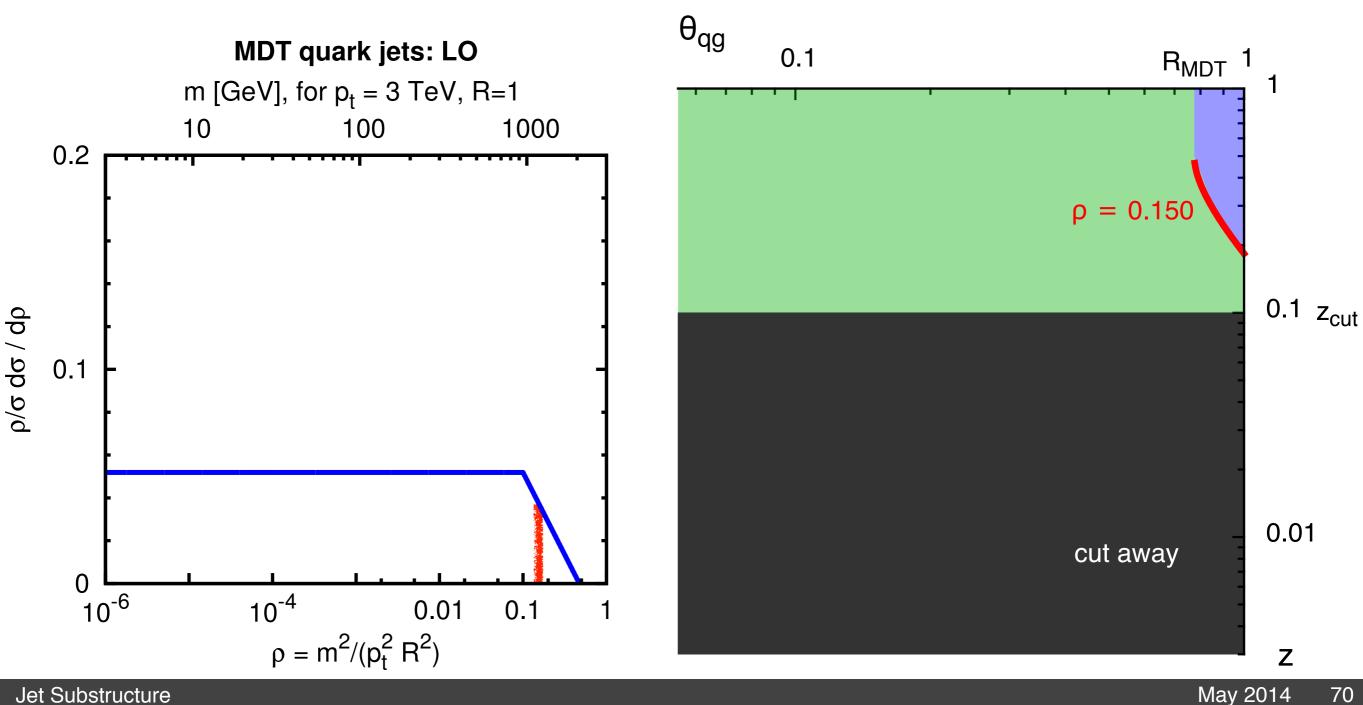

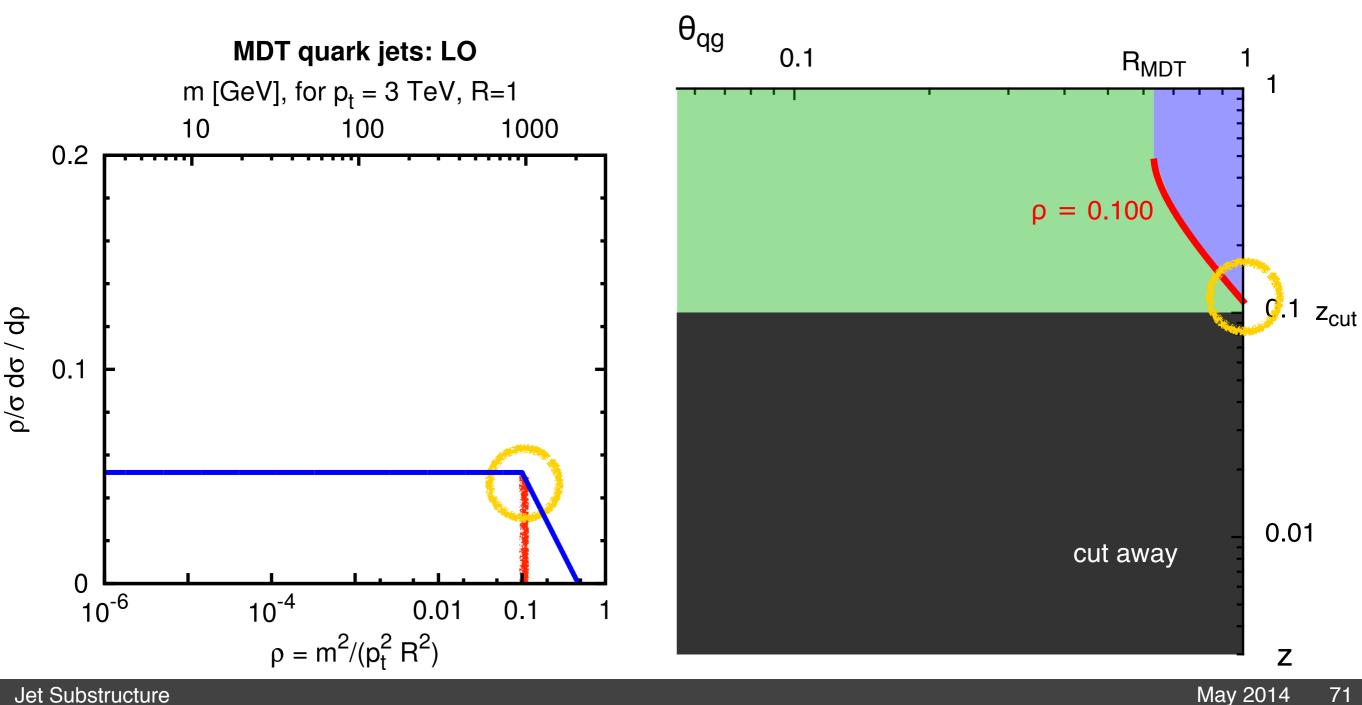

Jet is always split to give two subjets, and so y_{cut} (~ z_{cut}) is always applied.

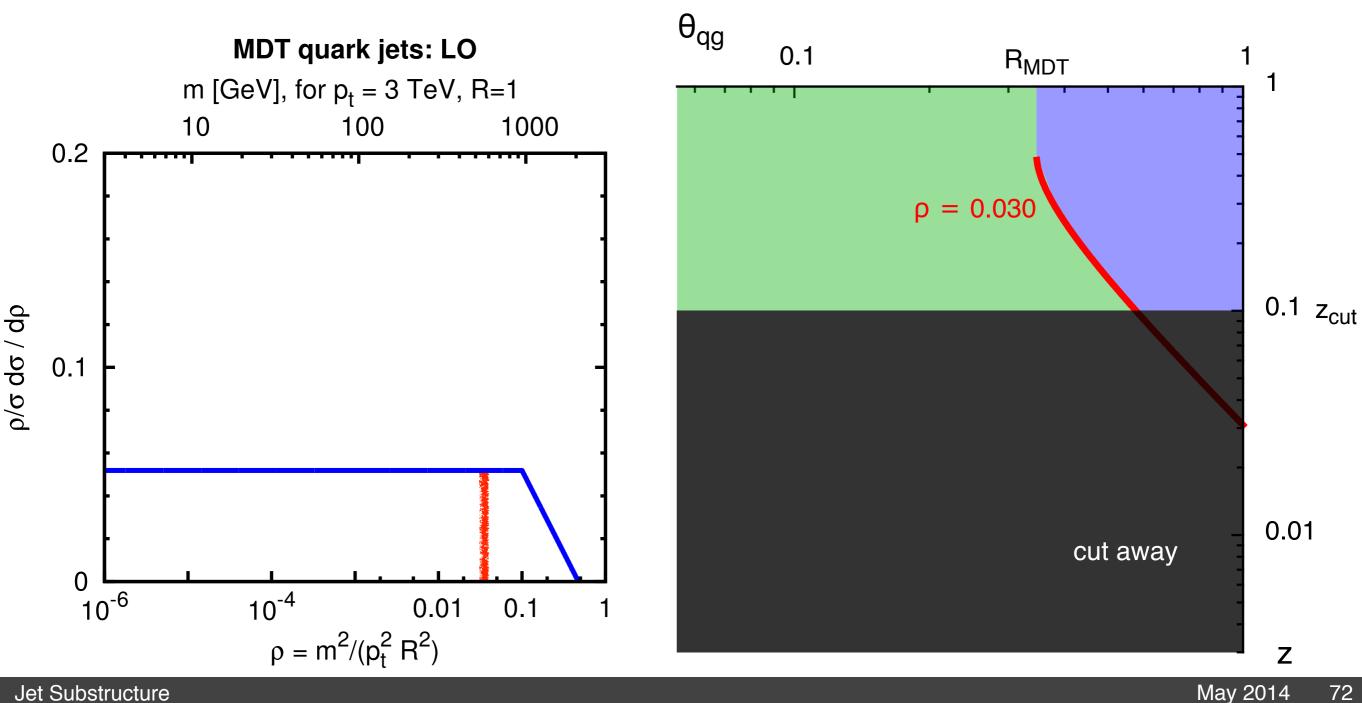

Jet is always split to give two subjets, and so y_{cut} $(\sim z_{cut})$ is always applied.

Jet is always split to give two subjets, and so y_{cut} $(\sim z_{cut})$ is always applied.

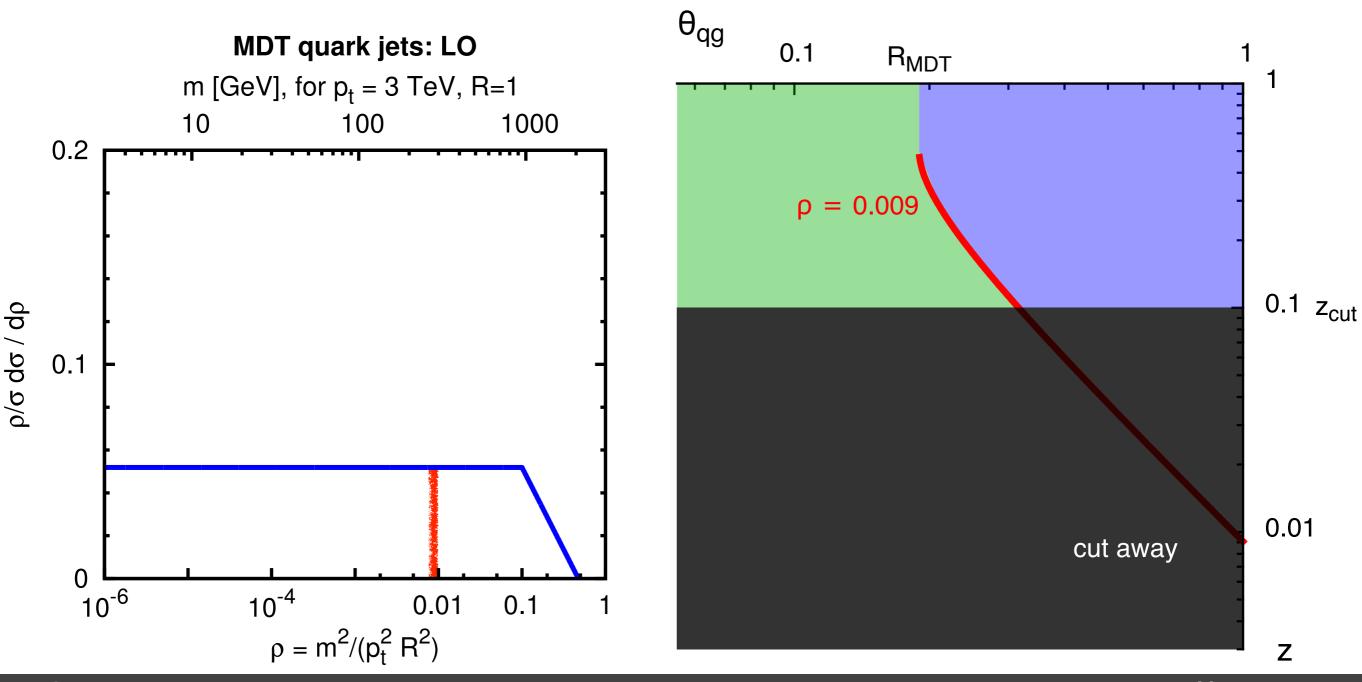

Jet is always split to give two subjets, and so y_{cut} $(\sim z_{cut})$ is always applied.

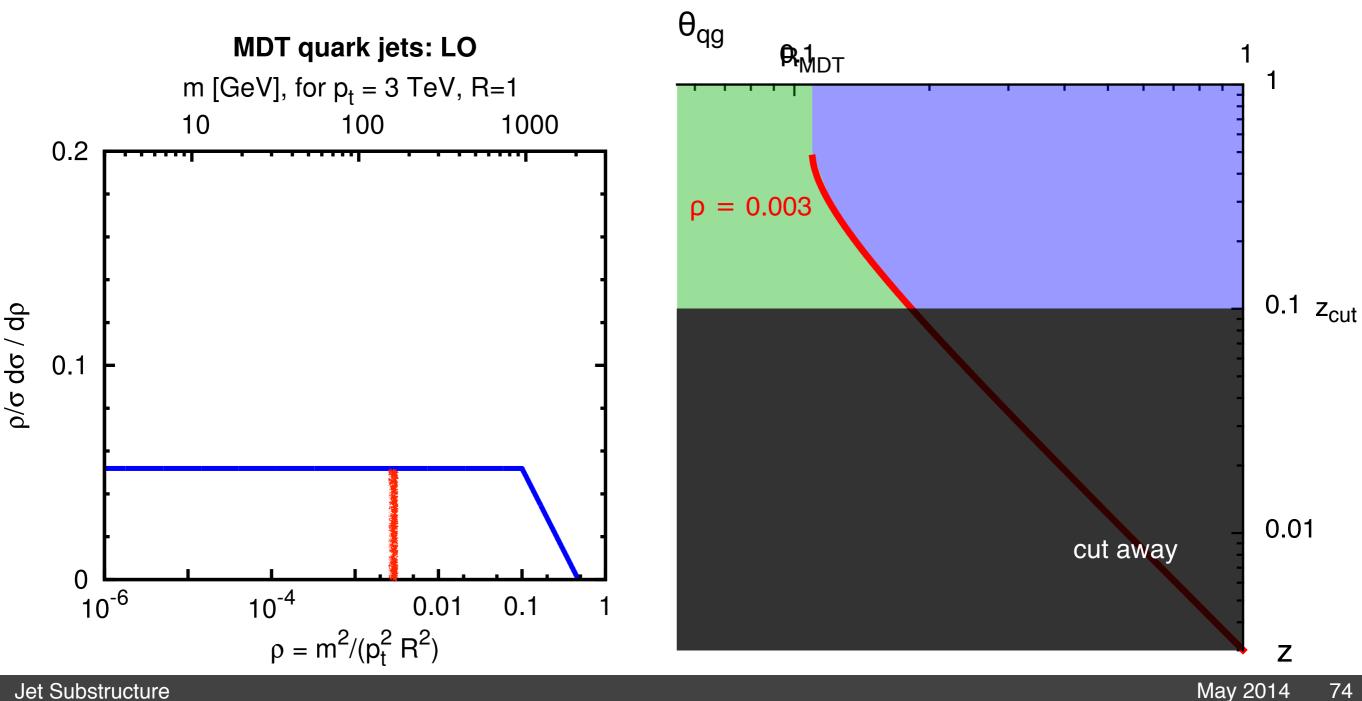

Jet Substructure

Jet is always split to give two subjets, and so y_{cut} (~ z_{cut}) is always applied.

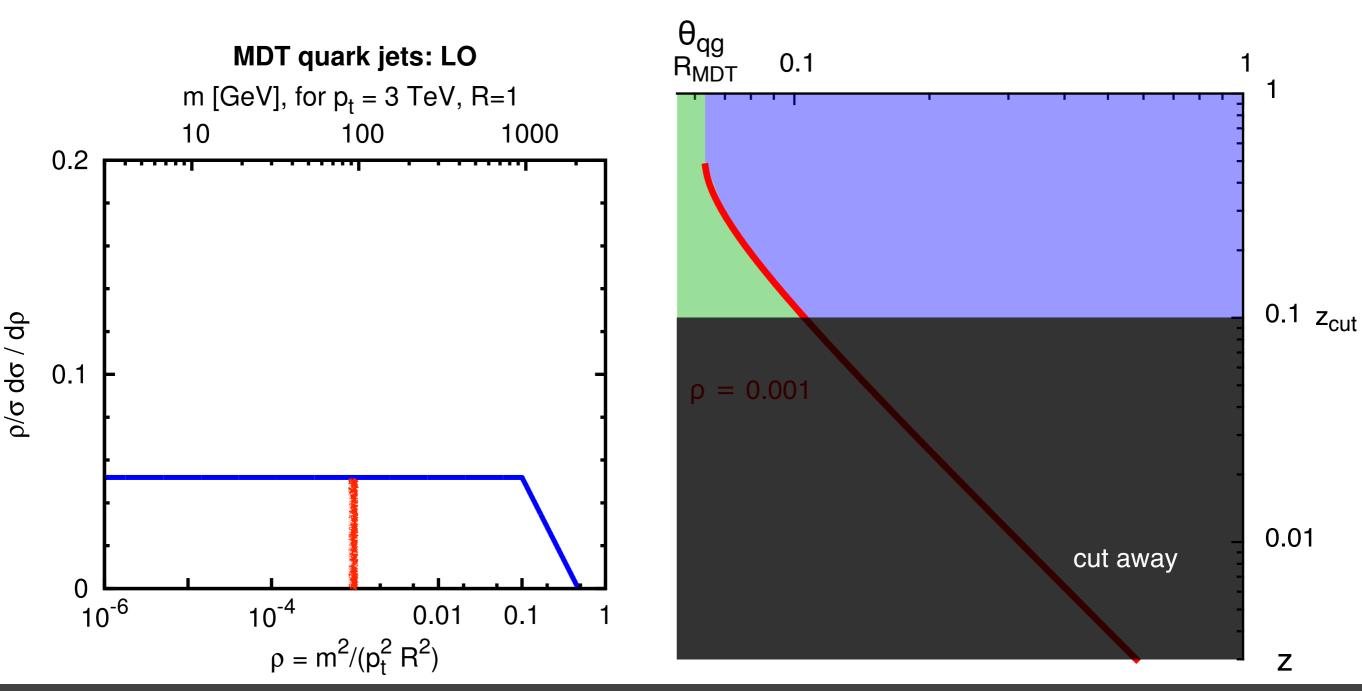

May 2014 73

Jet is always split to give two subjets, and so y_{cut} $(\sim z_{cut})$ is always applied.

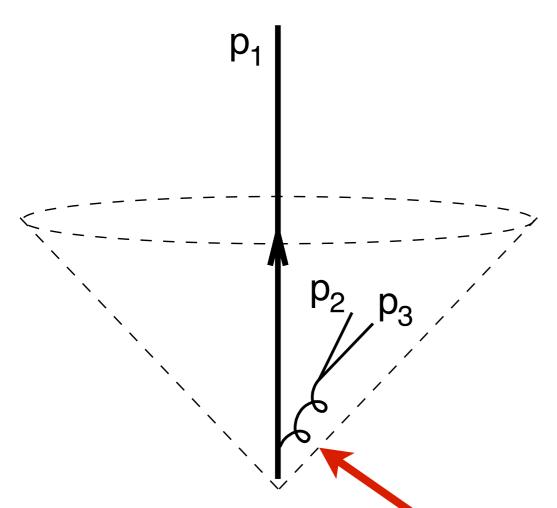

Jet Substructure

Jet is always split to give two subjets, and so y_{cut} (~ z_{cut}) is always applied.

May 2014 75

What MDT does wrong beyond LO:

Follows a soft branch (p₂+p₃ < y_{cut} p_{jet}) with "accidental" small mass, when the "right" answer was that the (massless) hard branch had no substructure

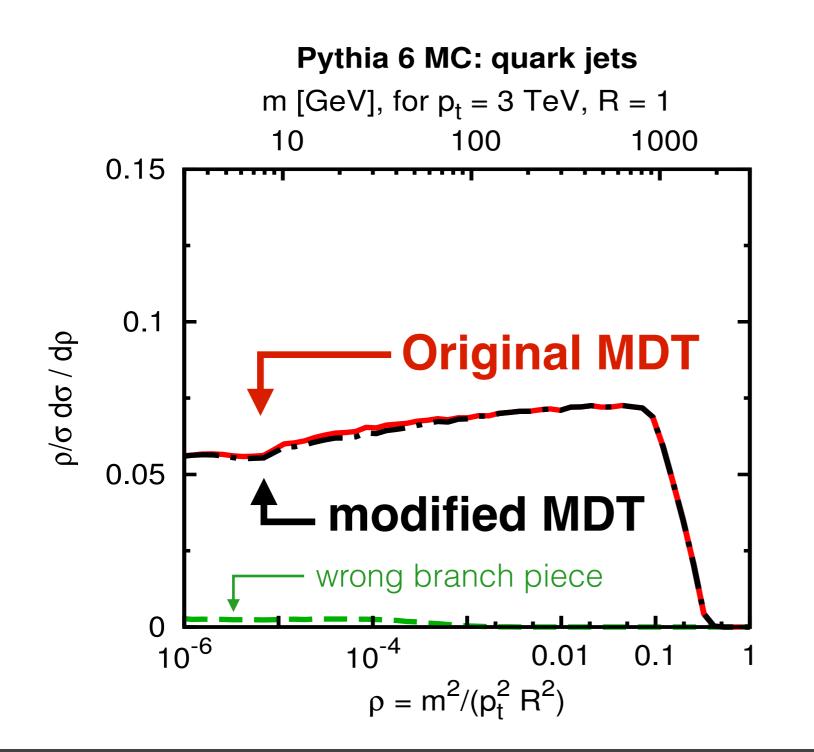

Subjet is soft, but has more substructure than hard subjet

MDT's leading logs (LL, in Σ) are:

$$\alpha_s L, \alpha_s^2 L^3, \dots$$
 I.e. $\alpha_s^n L^{2n-1}$

quite complicated to evaluate

A simple fix: **"modified"** Mass Drop Tagger: When recursing, **follow branch with larger (m²+p_t²)** (rather than the one with larger m)

Modification has almost no phenomenological impact, but big analytical consequences...

modified Mass Drop Tagger

At most "single logs", at all orders, i.e. $\alpha_s L, \, \alpha_s^2 L^2, \, \dots \, \text{I.e.} \, \alpha_s^n L^n$

Logs exclusively collinear – much simpler than jet mass

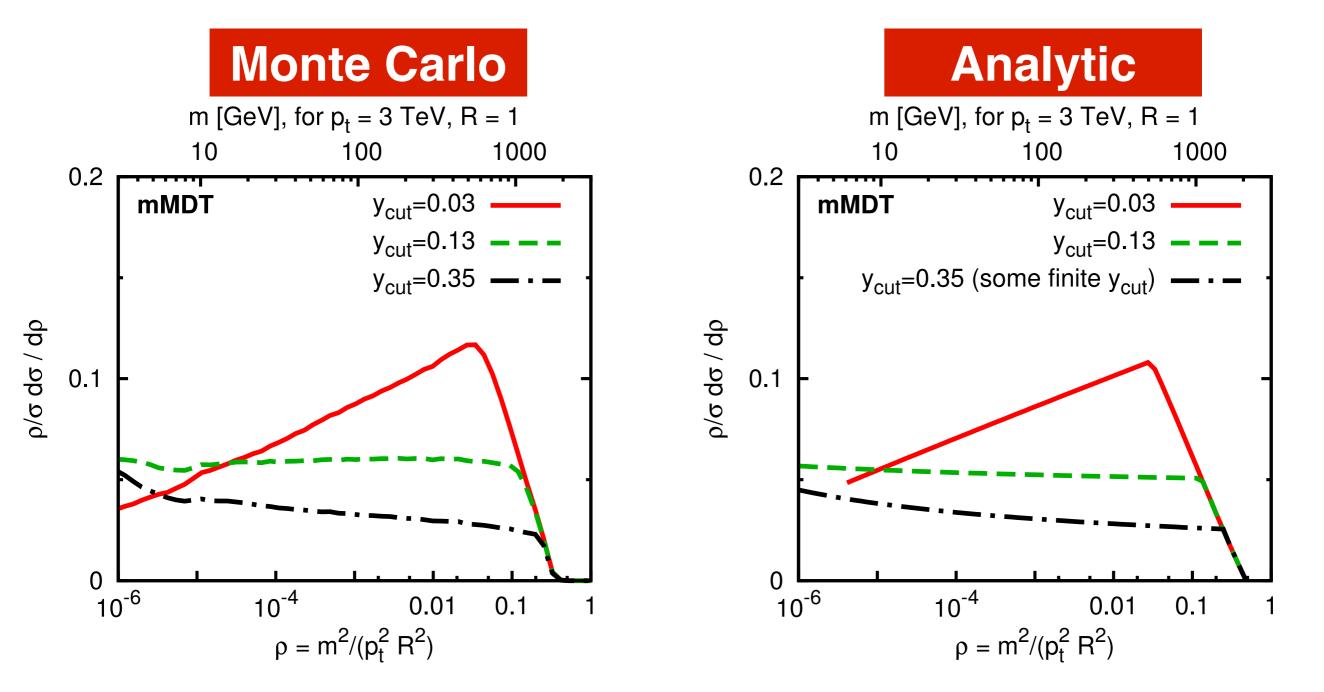

- no non-global logs
- no clustering logs
- no super-leading (factorization-breaking) logs First time anything like this has been seen

Fairly simple formulae; e.g. [fixed-coupling]

$$\Sigma^{(\mathrm{mMDT})}(\rho) = \exp\left[-\frac{\alpha_s C_F}{\pi} \left(\ln\frac{y_{\mathrm{cut}}}{\rho} \ln\frac{1}{y_{\mathrm{cut}}} - \frac{3}{4}\ln\frac{1}{\rho} + \frac{1}{2}\ln^2\frac{1}{y_{\mathrm{cut}}}\right)\right]$$

mMDT MC v. Resummation

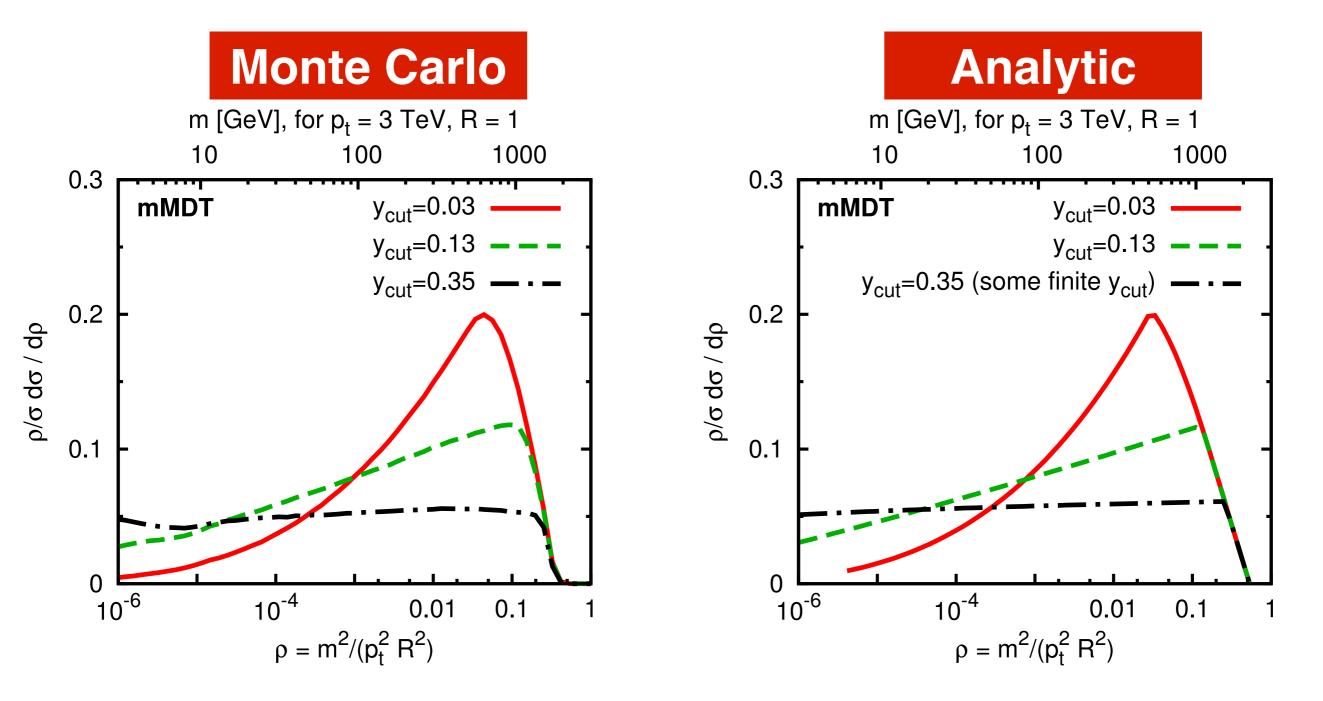

[mMDT is closest we have to a scale-invariant tagger, though exact behaviour depends on q/g fractions]

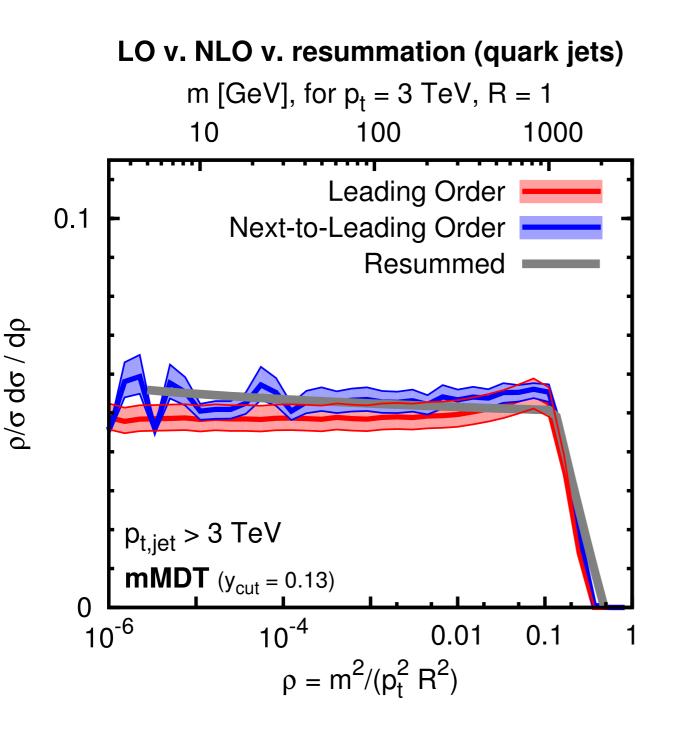

mMDT MC v. Resummation

gluon jets

[mMDT is closest we have to a scale-invariant tagger, though exact behaviour depends on q/g fractions]

mMDT resummation v. fixed order

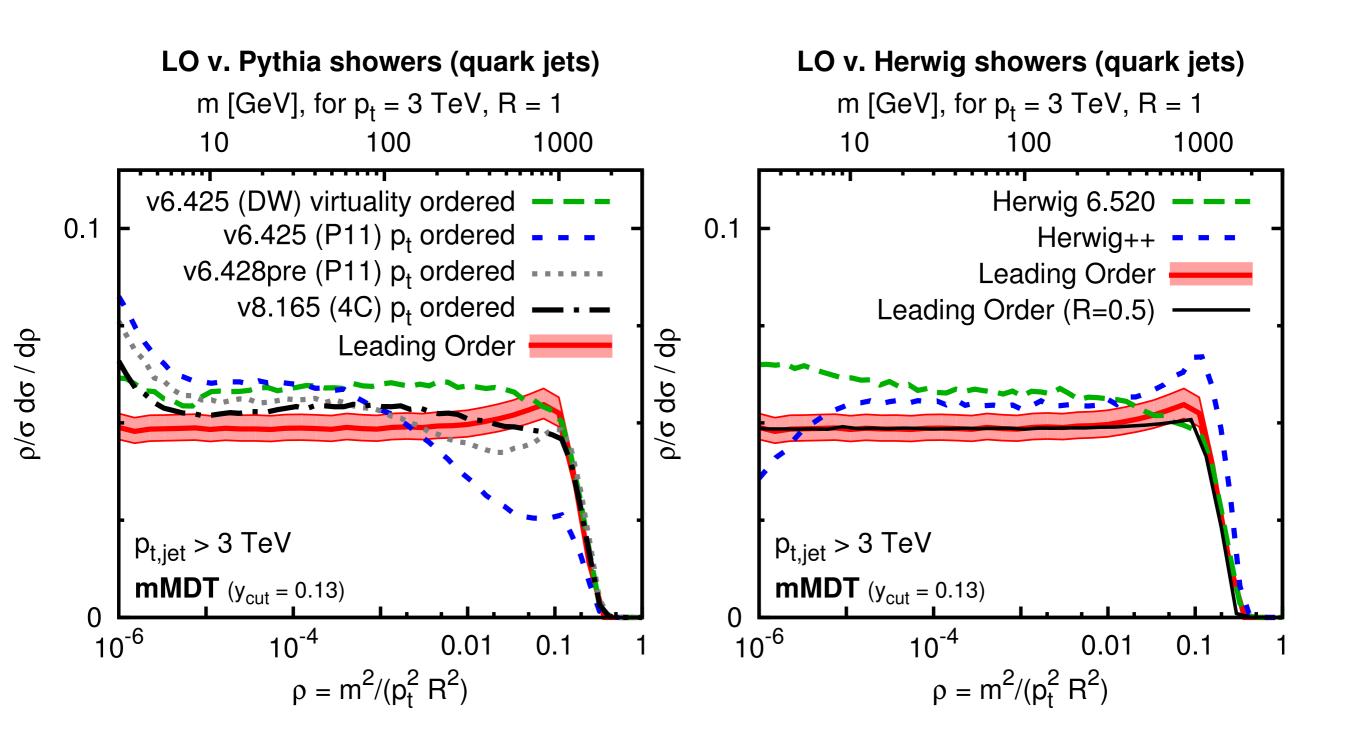

Because we only have single logs, fixed-order is valid over a broader than usual range of scales

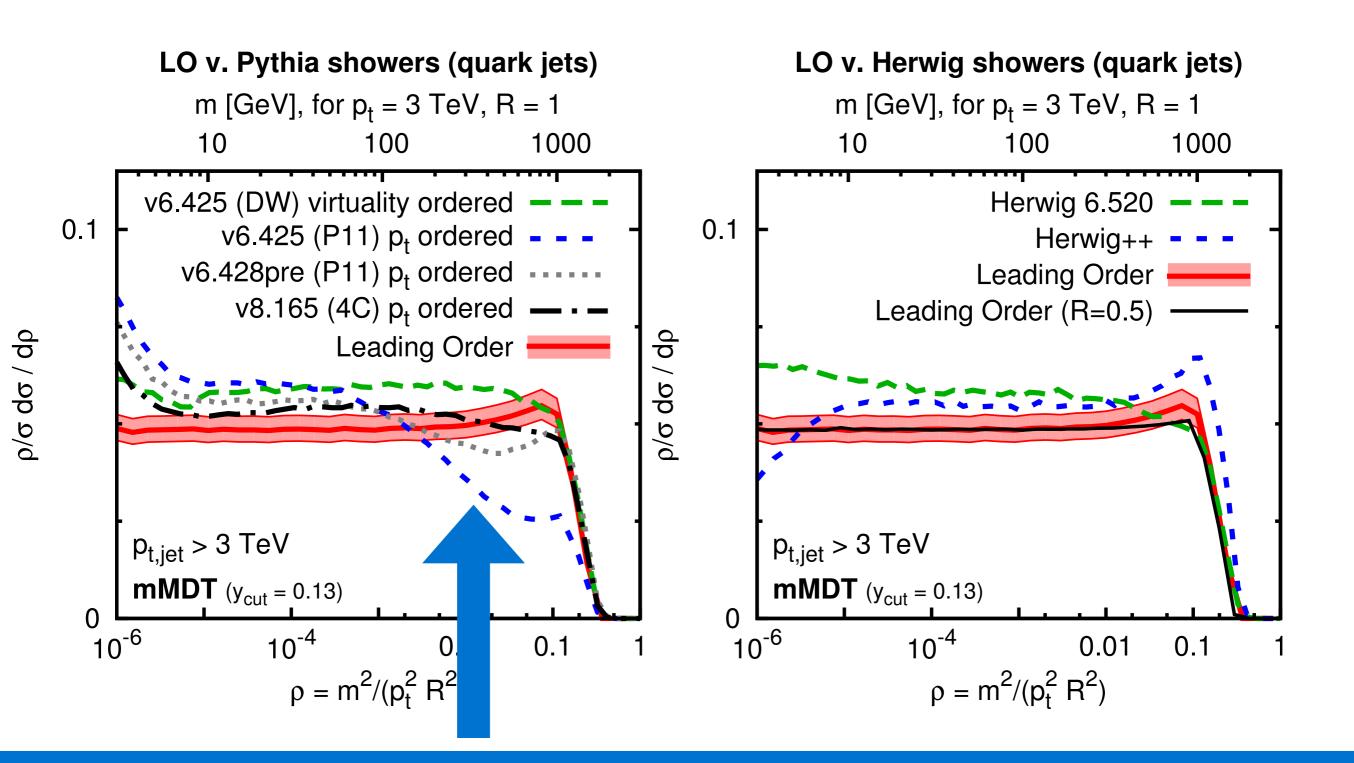

(helped by fortuitous cancellation between running coupling and single-log Sudakov)

NLO from NLOJet++

mMDT: comparing many showers

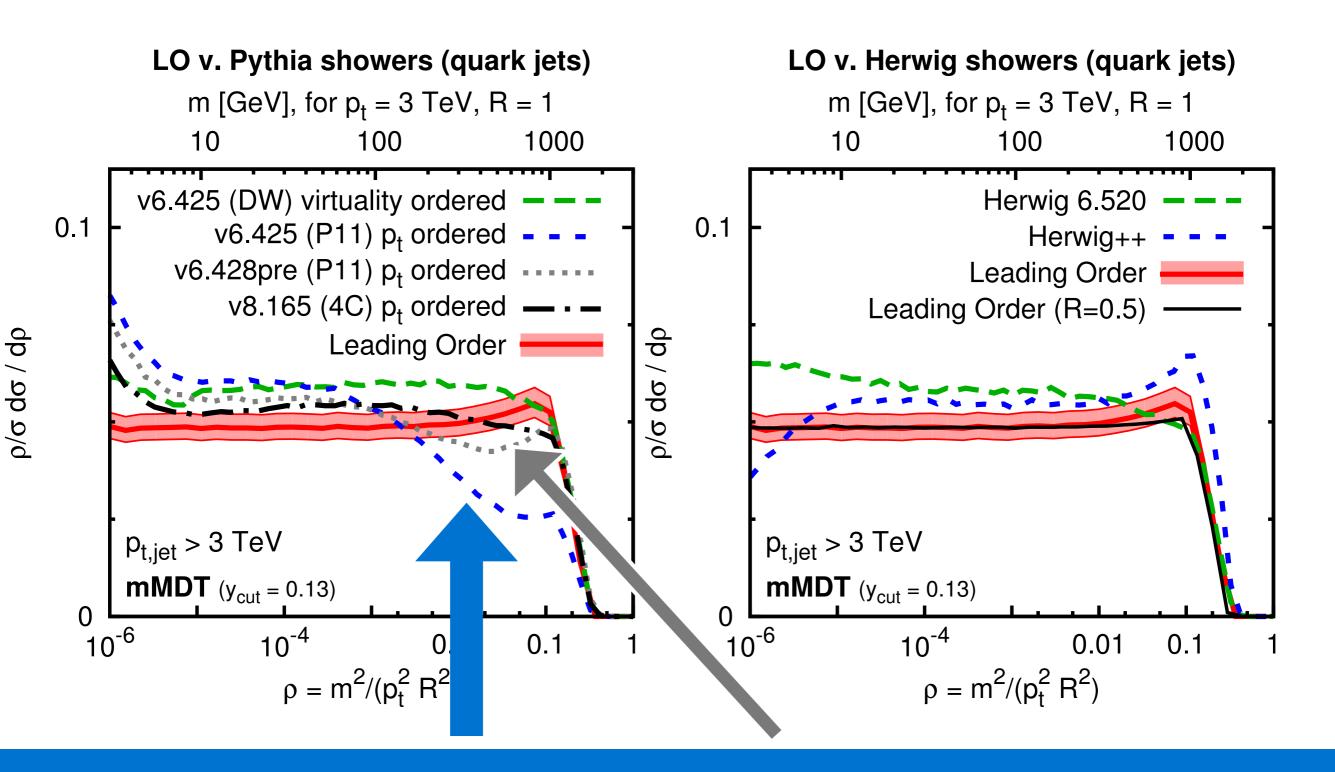

mMDT: comparing many showers

Issue found in Pythia 6 pt-ordered shower \rightarrow promptly identified and fixed by Pythia authors!

Jet Substructure

mMDT: comparing many showers

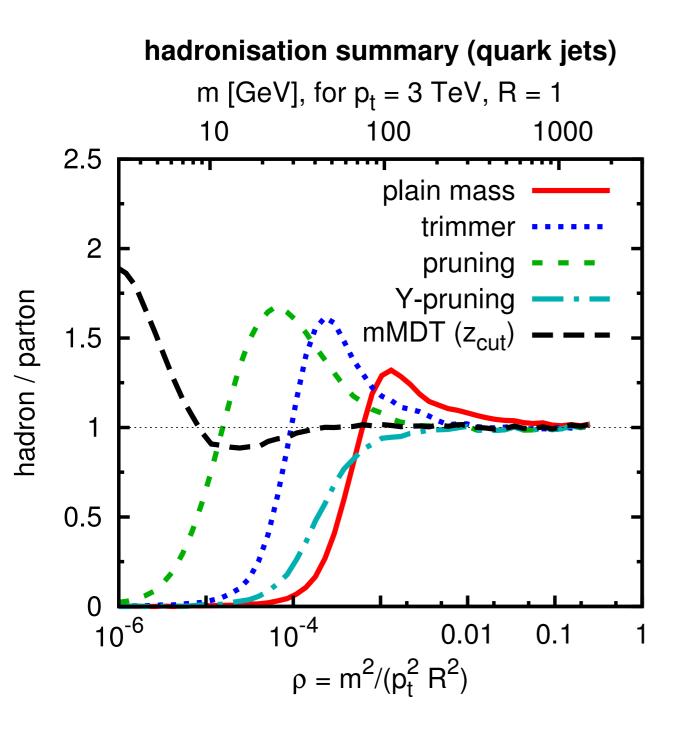

Issue found in Pythia 6 pt-ordered shower \rightarrow promptly identified and fixed by Pythia authors!

What about non-perturbative effects?

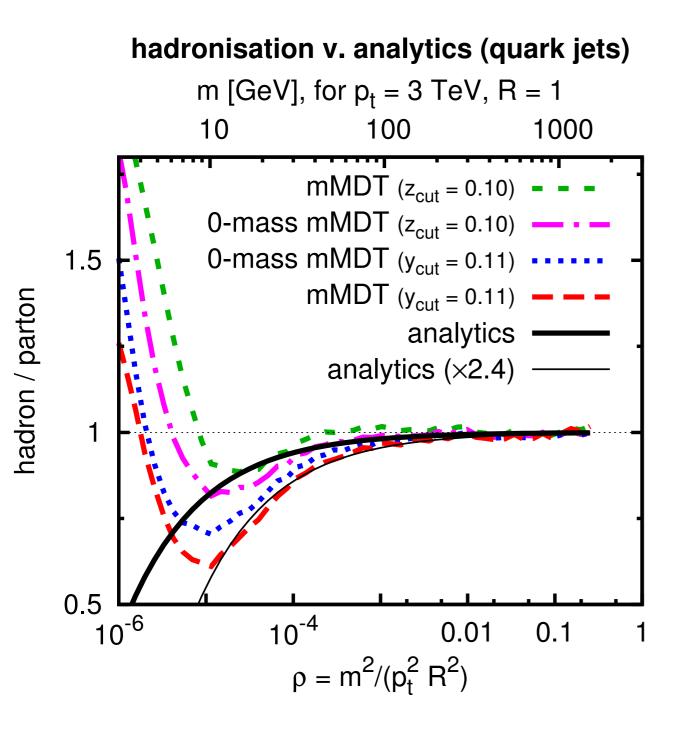

[on 3 TeV jets?!]

Hadronisation effects

Nearly all taggers have large hadronisation effects: 15 - 60%for m = 30 - 100 GeV

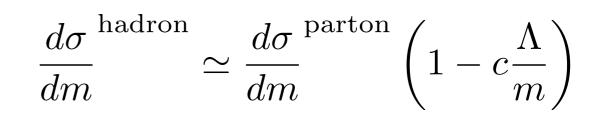

Hadronisation effects

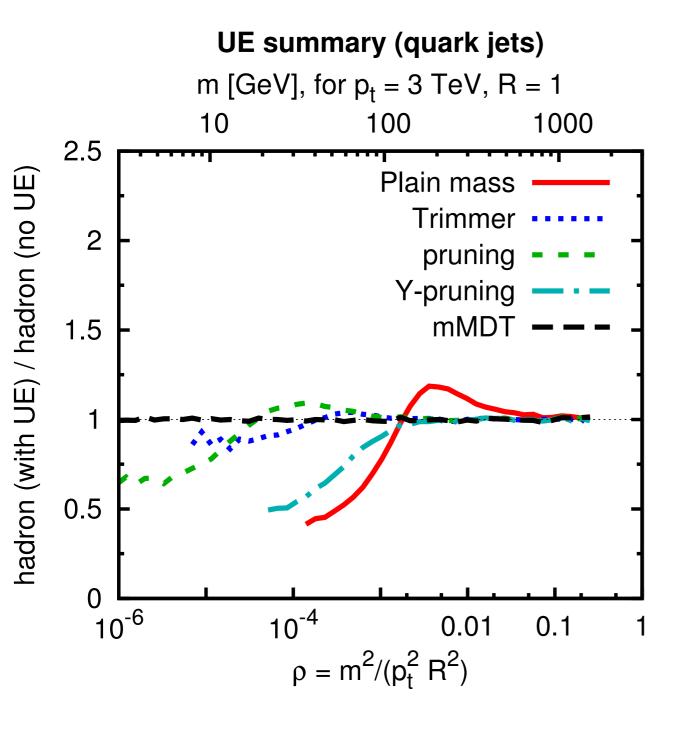

Exception is (m)MDT.

In some cases just few % effect.

m-dependence of hadronisation even understood analytically!

Underlying Event (UE)

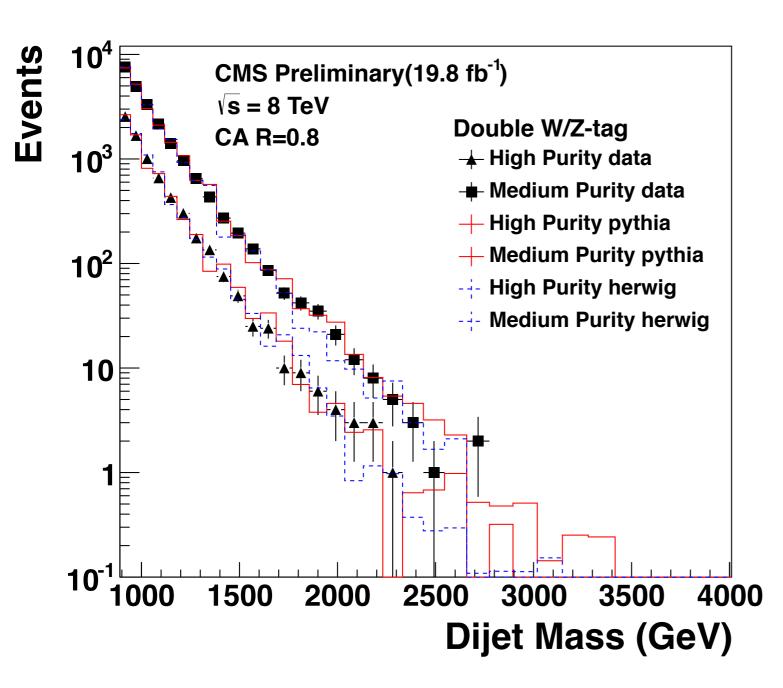

Underlying event impact much reduced relative to jet mass

Almost zero for mMDT (this depends on jet pt)

Does it matter?

In a way, that's a premature question Payoff is not intended to be immediate But let's still look at a couple of examples

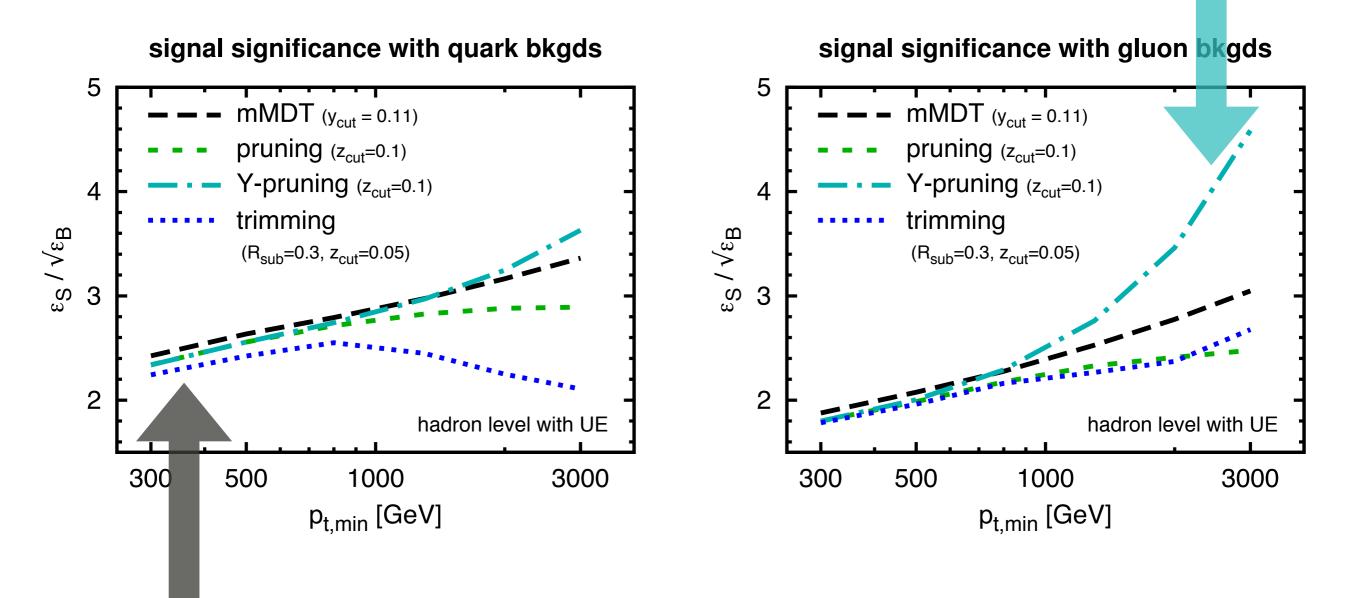

Search for resonances in doubly-tagged dijet events.

Tagging = pruning + tau21 cut

Note different Herwig++ and Pythia6 shapes

Performance for finding signals (S/ \sqrt{B})

At high pt, substantial gains from new Y-pruning (probably just indicative of potential for doing better)

At low pt (moderate m/pt), all taggers quite similar

Summary

- Use of jets beyond the *"jet=parton"* idea is with us today.
- That puts a responsibility on theorists to start understanding jet substructure beyond simply running Monte Carlos.
- It seems that's feasible, with the potential also to guide development of more powerful and more robust jet tools.
- Hopefully, this will help reliably stretch the boundaries of what LHC can do in its searches and measurements!

Bottom line on "understanding"

- Taggers may be quite simple to write, but potentially involved to understand.
- Contrast this with pt cuts for standard jet analyses (mostly) simple
- Still, many taggers/groomers are within calculational reach.
- New "modified" Mass Drop Tagger is especially simple
- New Y-pruning is also interesting further investigation warranted...

Summary table

					_
	highest logs	transition(s)	Sudakov peak	NGLs	-
plain mass	$\alpha_s^n L^{2n}$		$L \simeq 1/\sqrt{\bar{\alpha}_s}$	yes	-
trimming	$\alpha_s^n L^{2n}$	$z_{ m cut}, r^2 z_{ m cut}$	$L \simeq 1/\sqrt{\bar{\alpha}_s} - 2\ln r$	yes	-
pruning	$\alpha_s^n L^{2n}$	$z_{ m cut},z_{ m cut}^2$	$L \simeq 2.3 / \sqrt{\bar{\alpha}_s}$	yes	
MDT	$\alpha_s^n L^{2n-1}$	$y_{\mathrm{cut}}, \frac{1}{4}y_{\mathrm{cut}}^2, y_{\mathrm{cut}}^3$		yes	_
Y-pruning	$\alpha_s^n L^{2n-1}$	$z_{ m cut}$	(Sudakov tail)	yes	NEW
mMDT	$lpha_s^n L^n$	$y_{ m cut}$	—	no	
Special: only single			Special: better		

logarithms (L = ln ρ)

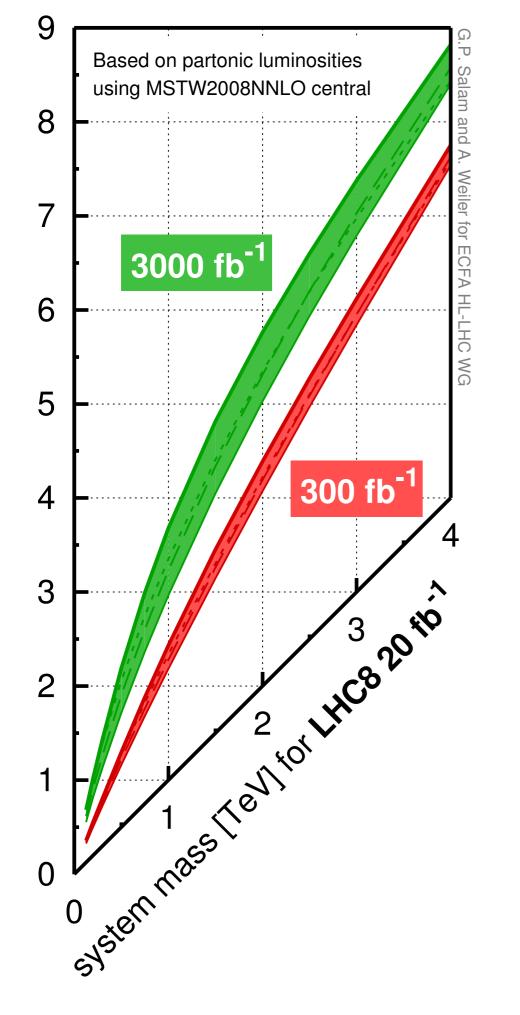

→ more accurately calculable

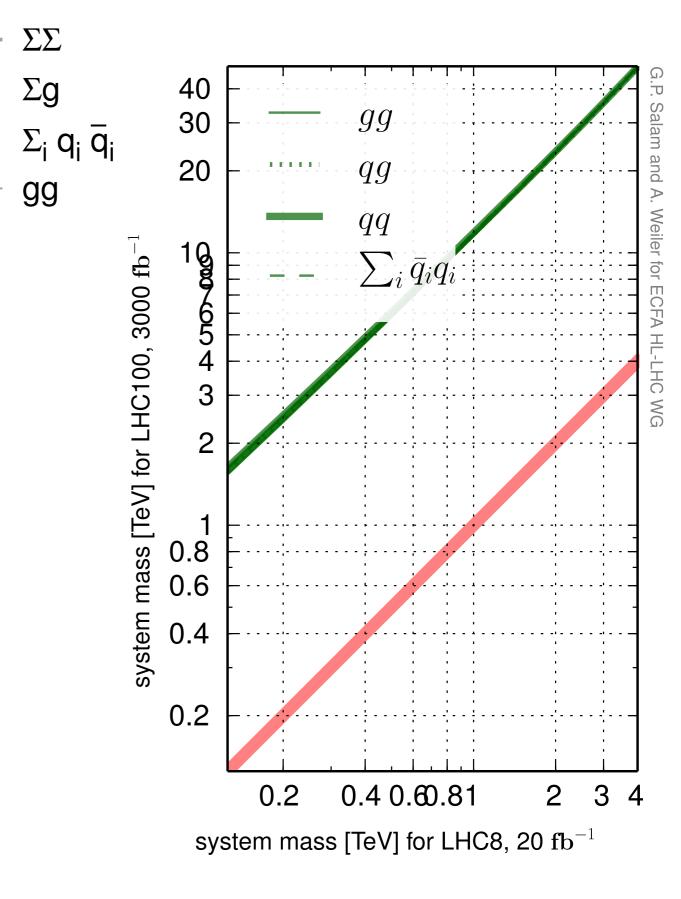

Special: better exploits signal/bkgd differences

EXTRAS

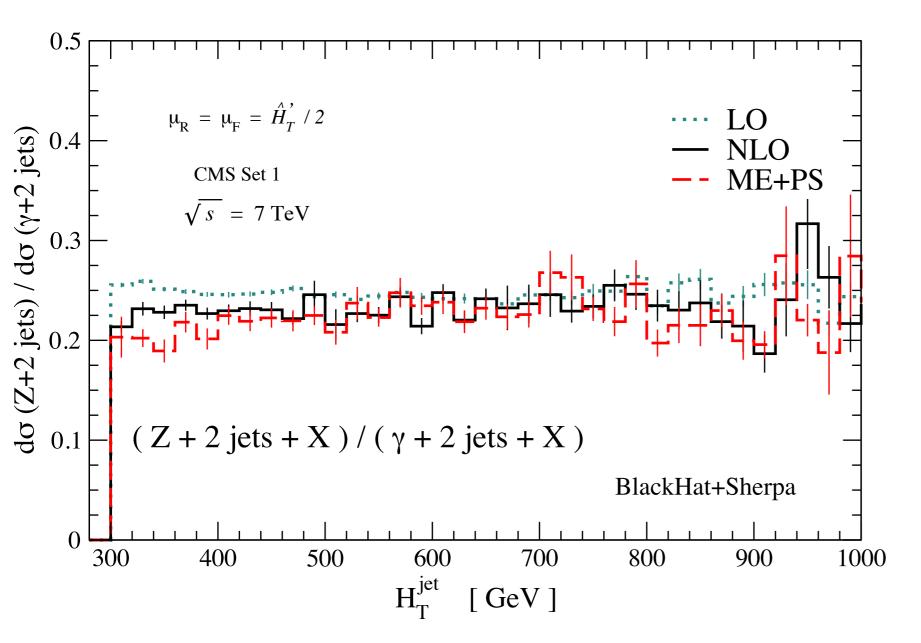

Understanding your taggers means you know what tools you can safely use with them

For robustness, you can then choose taggers whose distributions can be predicted in many ways

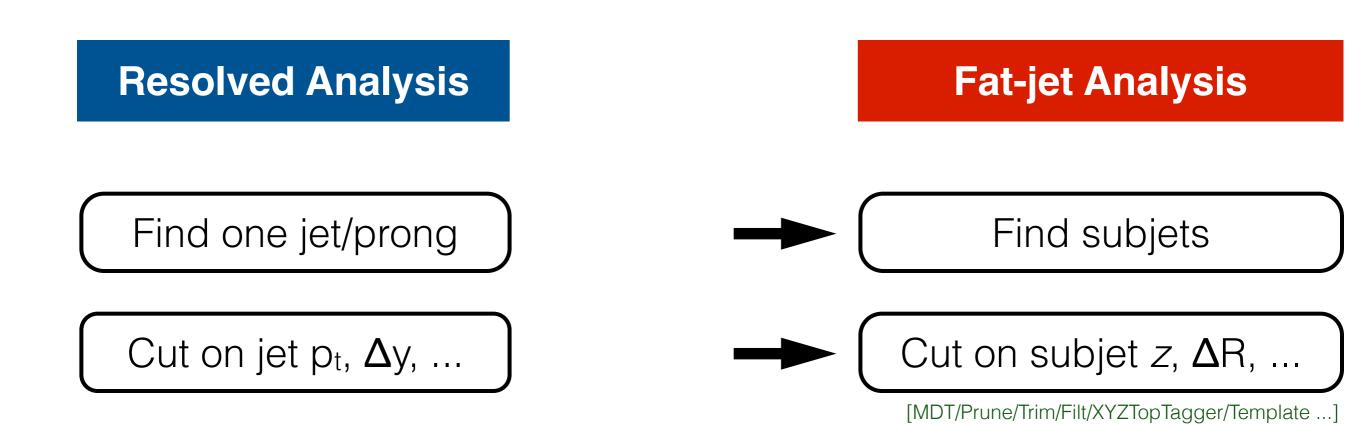

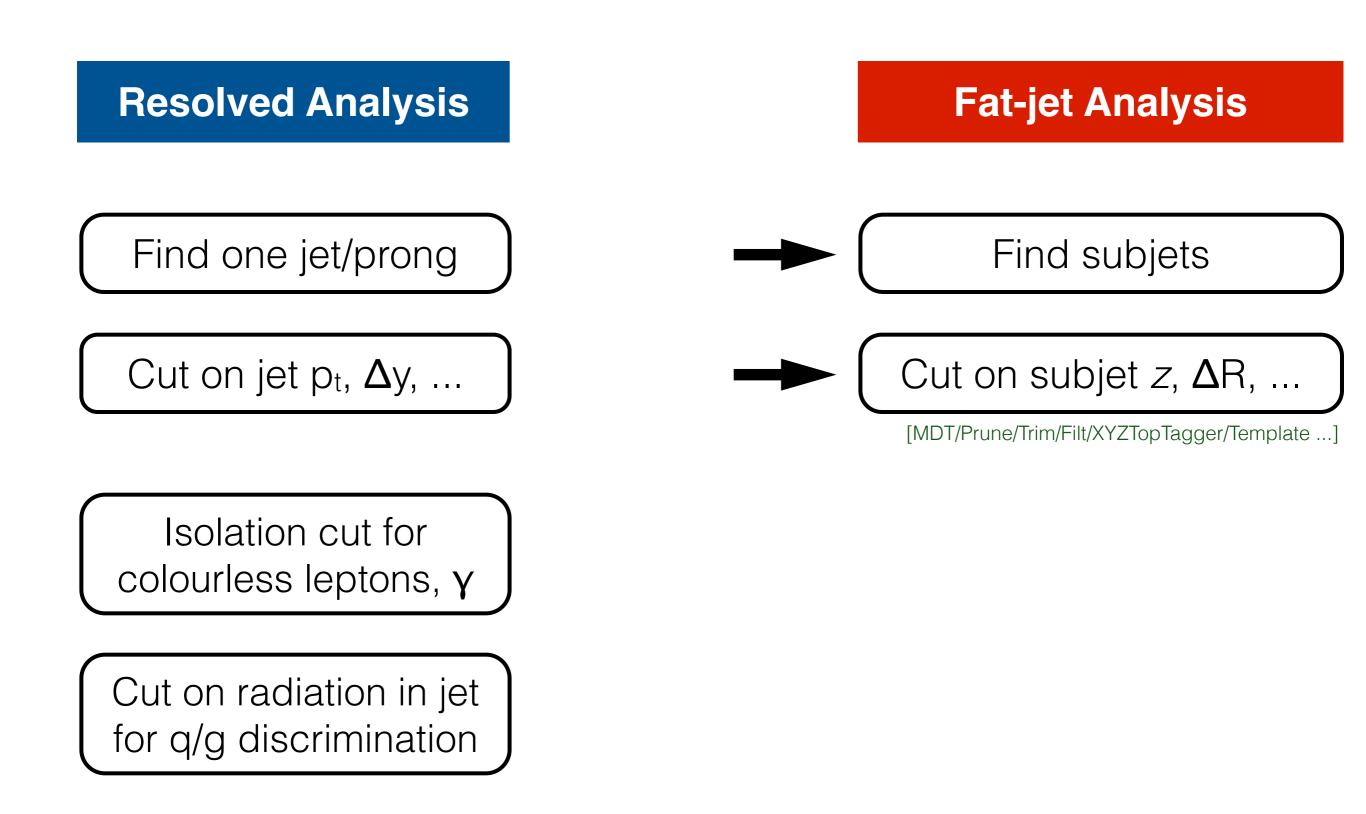

Just like MET($Z \rightarrow vv$) in multijets is reliably estimated from γ +jets because multiple types of calculations of the ratio agree

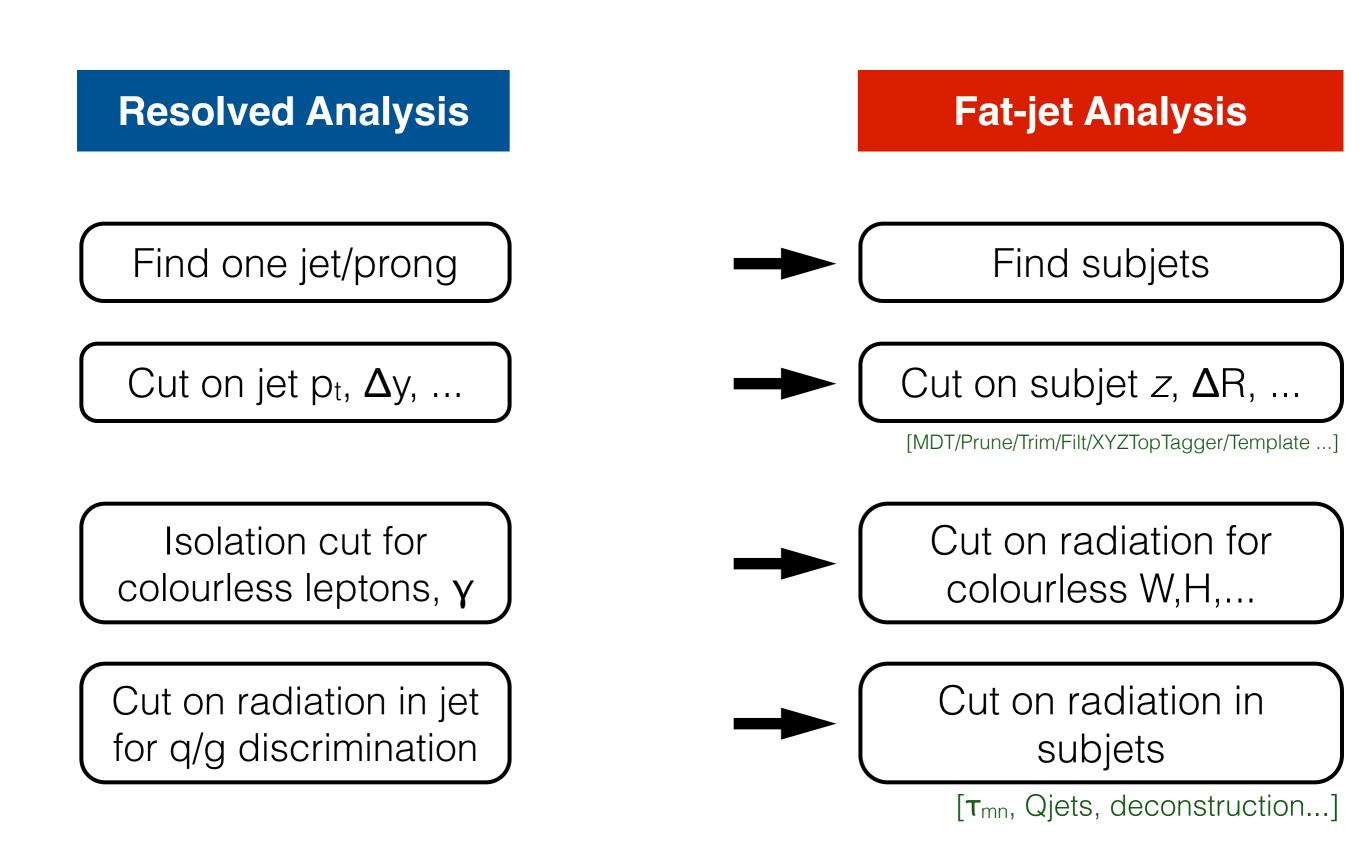

Resolved Analysis

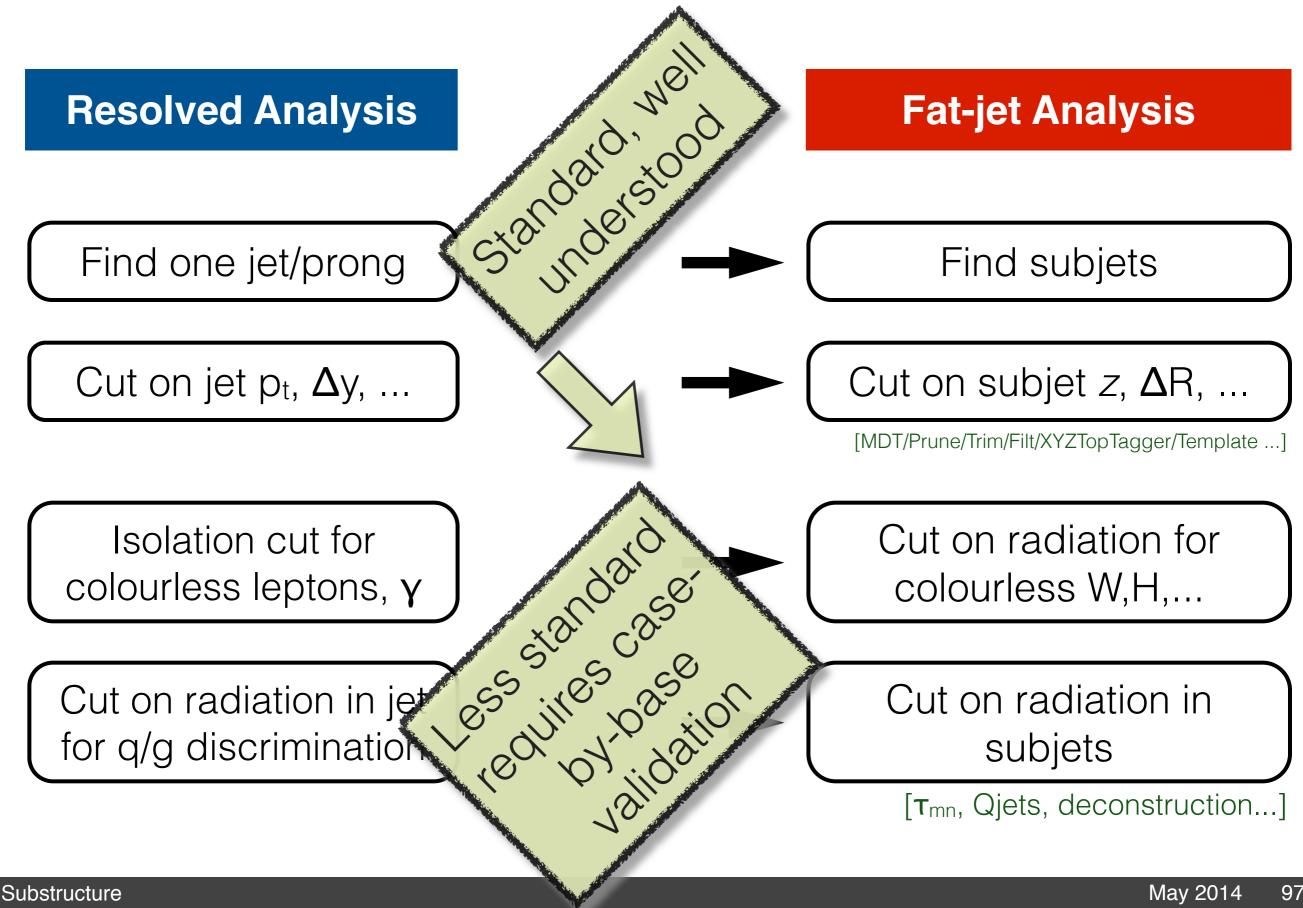

Find one jet/prong

Cut on jet p_t , Δy , ...

Different fat-jet tagger types

Prong based

(e.g. HEPTopTagger, Template Tagger)

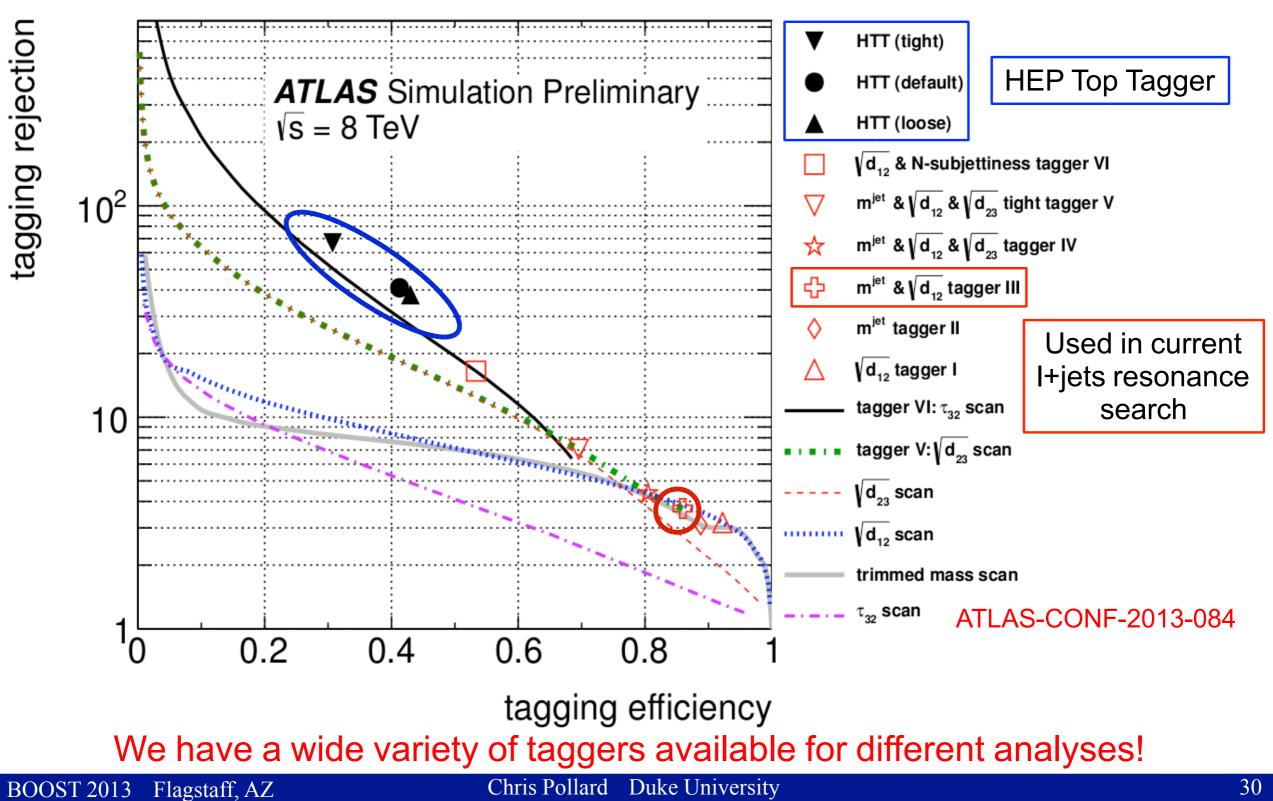

Identifies prongs

 Requires prongs be consistent with kinematics of t→Wb→ 3 guarks

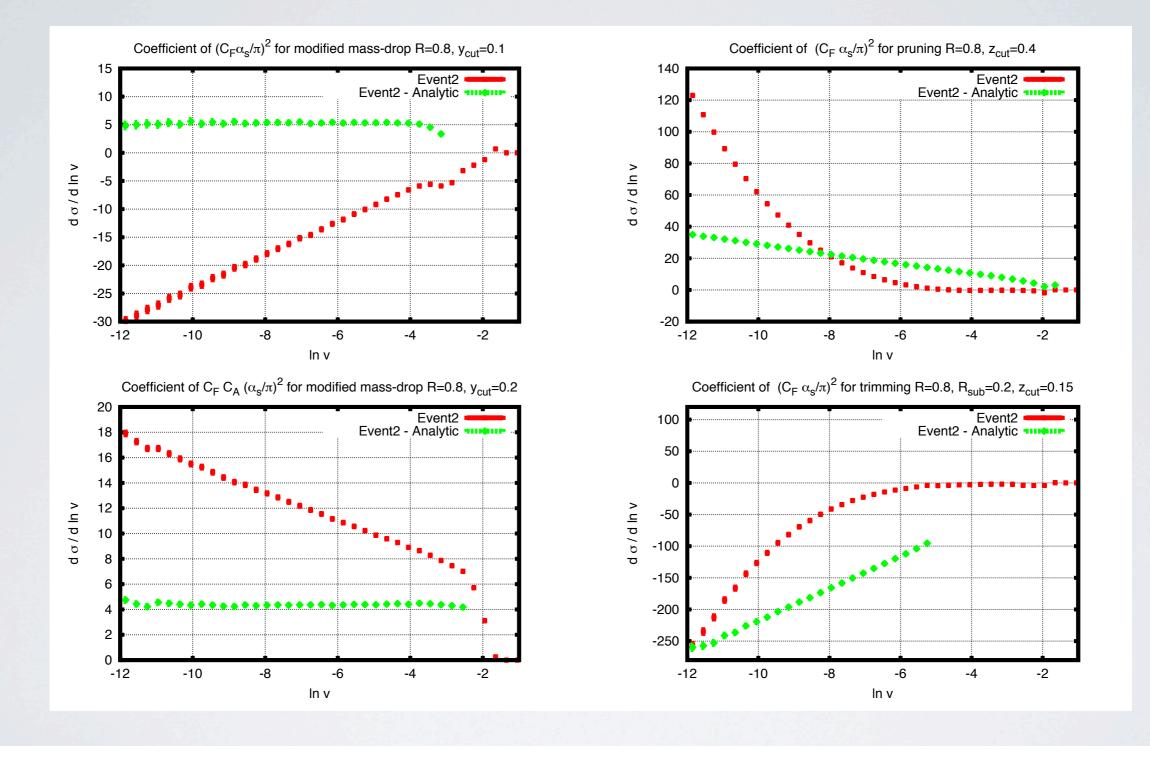

Radiation based

- (e.g. N-subjettiness = τ_3/τ_2 + mass cut)
- Requires top-mass consistency (maybe with some grooming)
- Exploits weaker radiation from top (3 quarks) than background (1q+2g or 3g)

Top Tagger Comparison

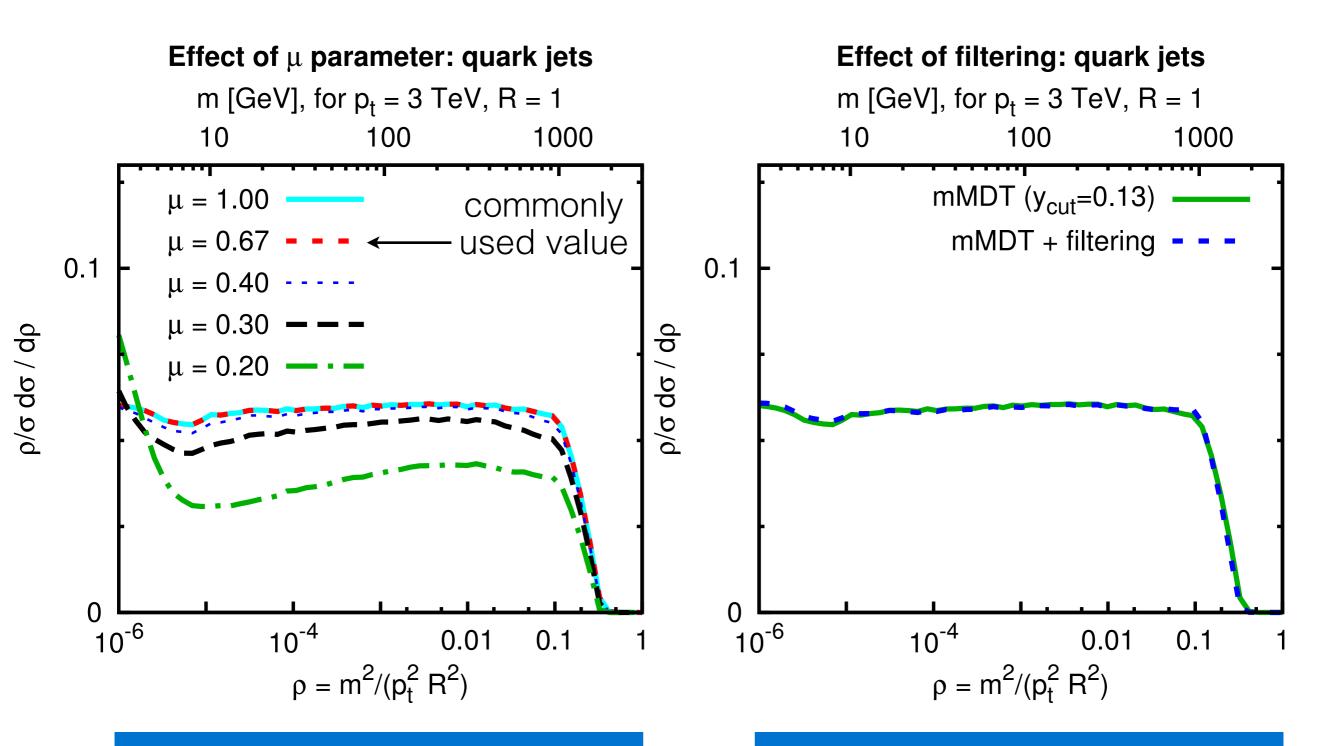

Examples of NLO checks

Dasgupta, Fregoso, Marzani & Powling, 1307.0013

mMDT: impact of μ and of filtering

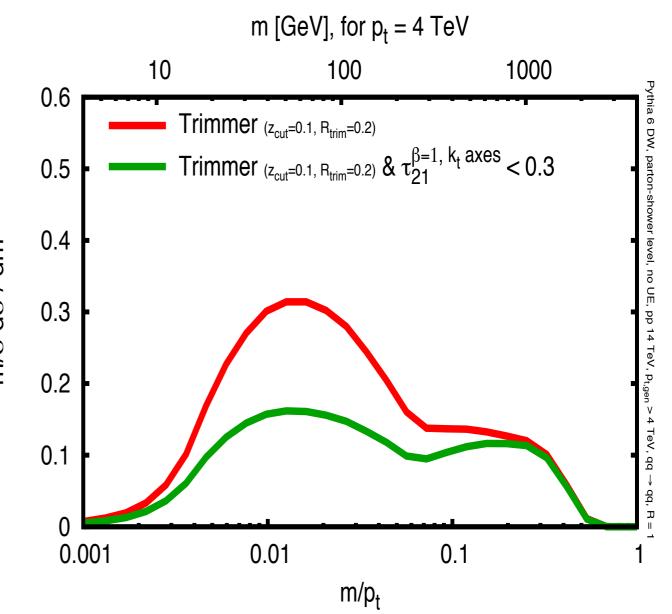

μ parameter basically irrelevant (simpler tagger discards it)

filtering leaves results unchanged (up to and incl. NNLL)

What about cuts on shapes/radiation

E.g. cuts on N-subjettiness, tight mass drop, etc.?

- These cuts are nearly always for a jet whose mass is somehow groomed. All the structure from the grooming persists.
- So tagging & shape must probably be calculated together

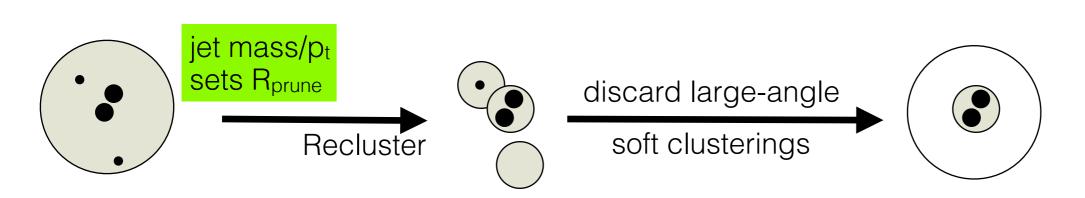

Take a jet and define $R_{prune} = m / p_t$ Recluster with k_t or C/A alg. At each i+j clustering step, if $p_{ti} \text{ Or } p_{tj} < \mathbf{Z_{cut}} p_{t(i+j)asdf}$ $\Delta R_{ij} > R_{prune}$ discard softer prong. Acts similarly to filtering, but with dynamic subjet radius

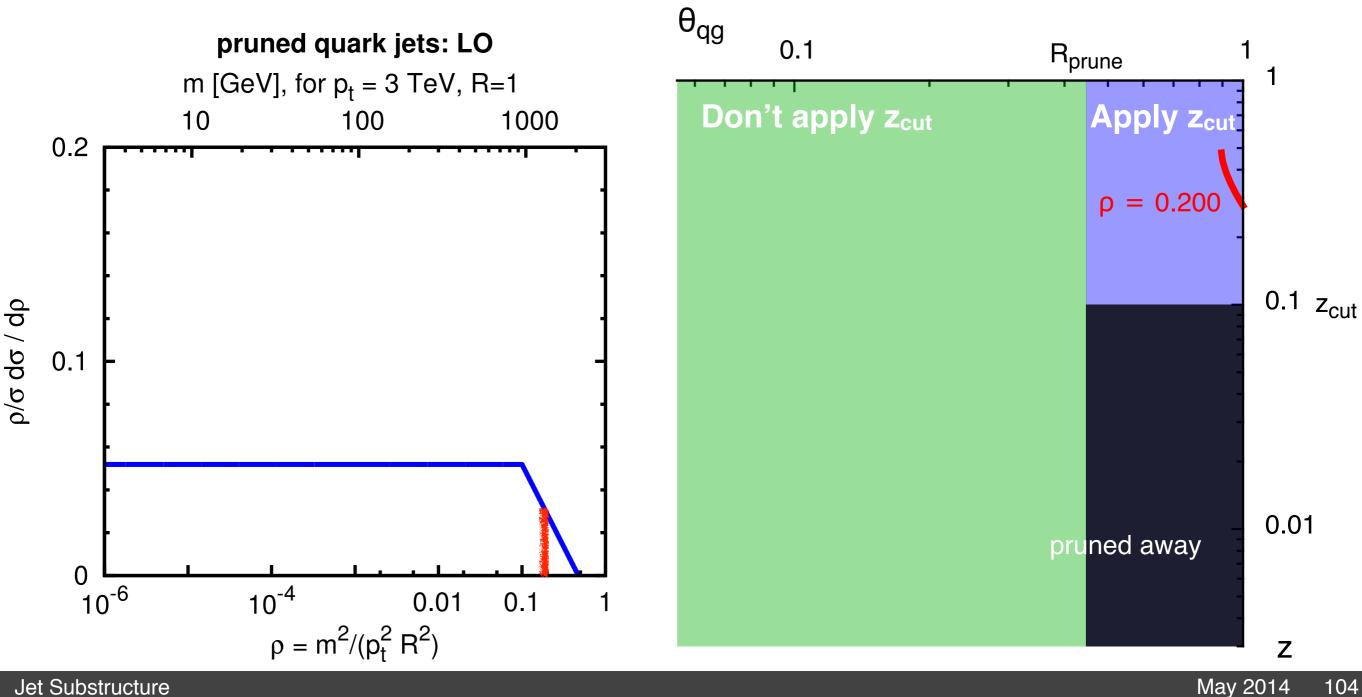

Pruning Ellis, Vermillion & Walsh '09

one (main) parameter: *z*_{cut}

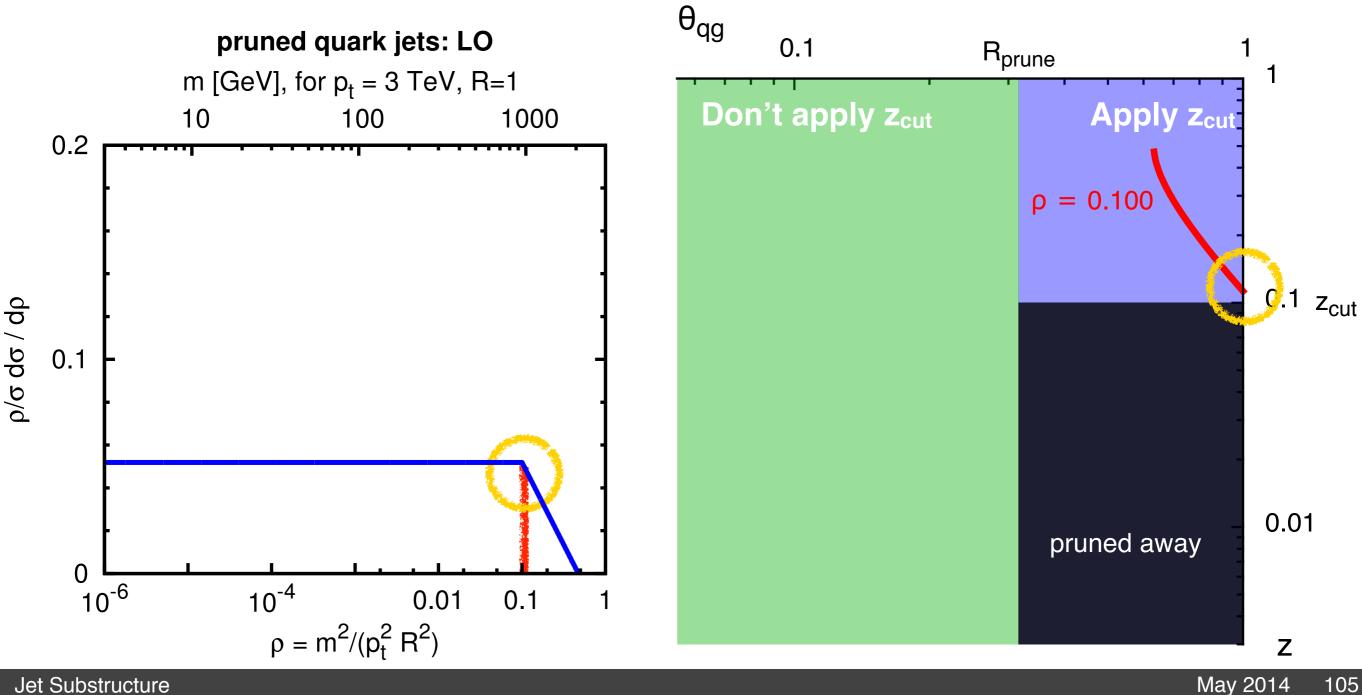

we'll study variant with C/A reclustering

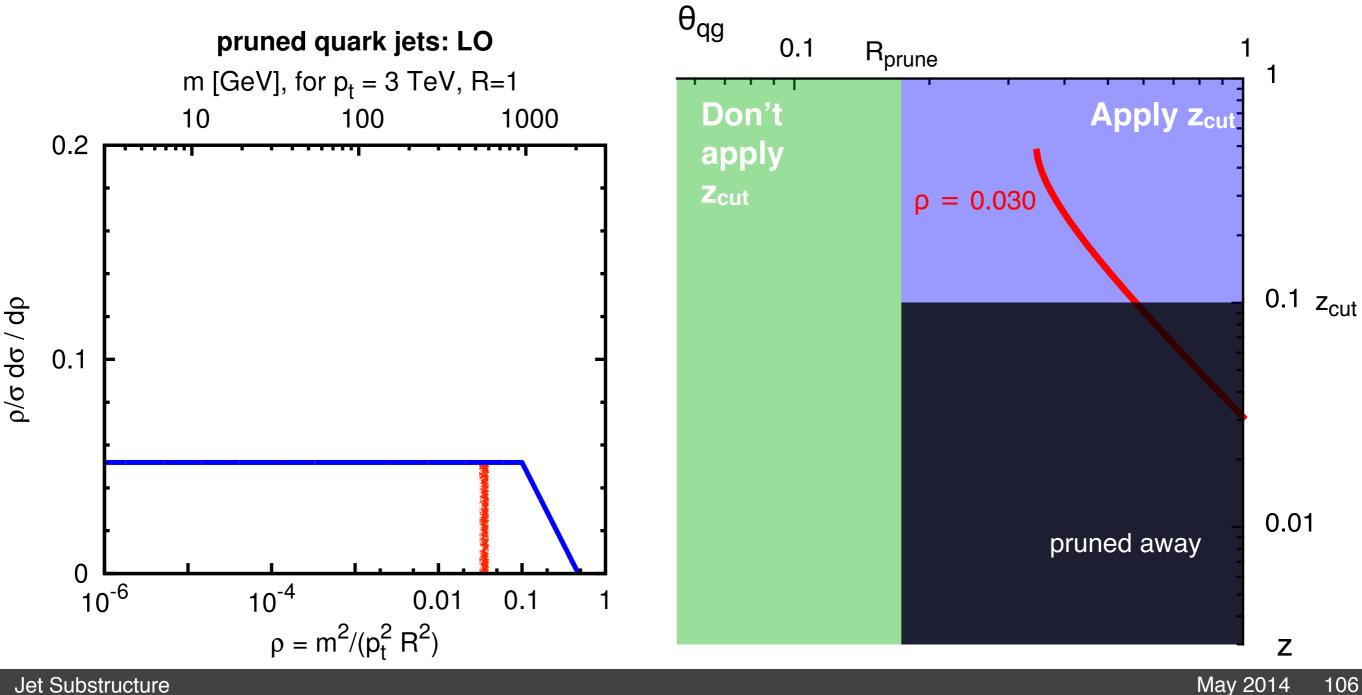

Dynamical choice of R_{prune} means that two prongs are always separated by $> R_{prune}$. So, unlike trimming, *z*_{cut} always applied.

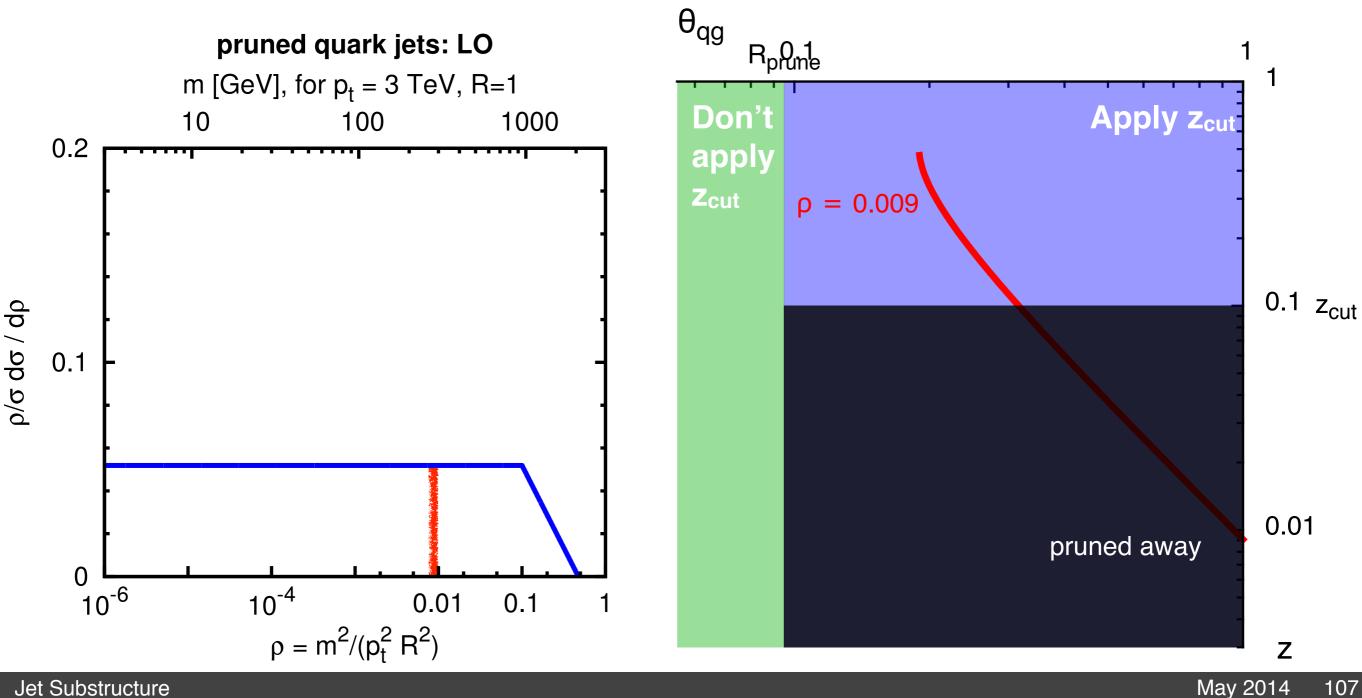

Dynamical choice of R_{prune} means that two prongs are always separated by $> R_{prune}$. So, unlike trimming, *z*_{cut} always applied.

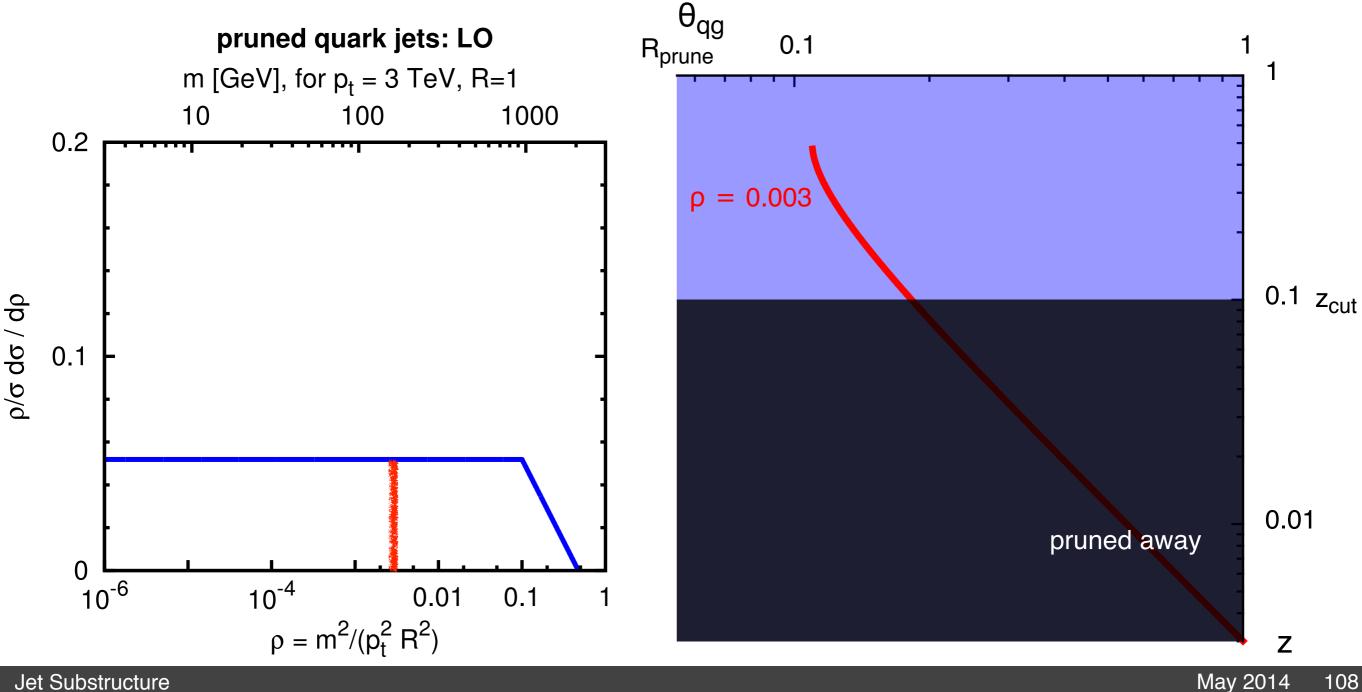

Dynamical choice of R_{prune} means that two prongs are always separated by $> R_{prune}$. So, unlike trimming, *z*_{cut} always applied.

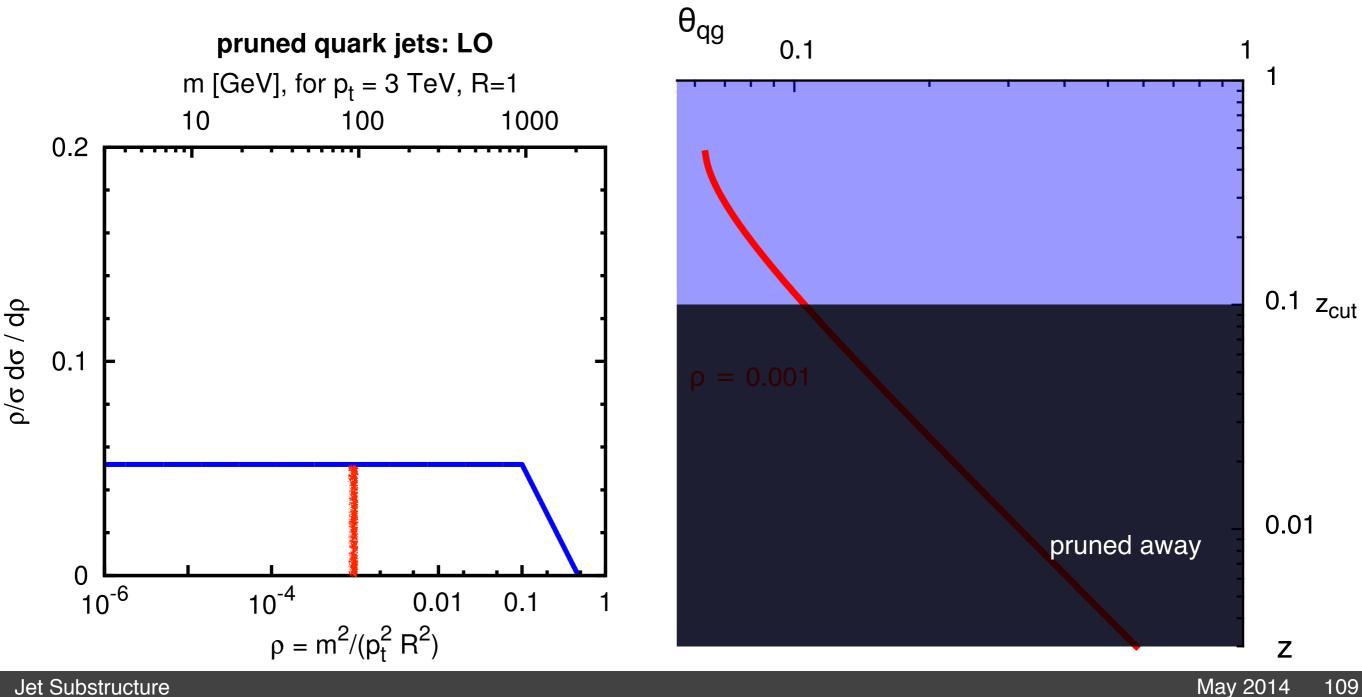

Dynamical choice of R_{prune} means that two prongs are always separated by $> R_{prune}$. So, unlike trimming, *z*_{cut} always applied.

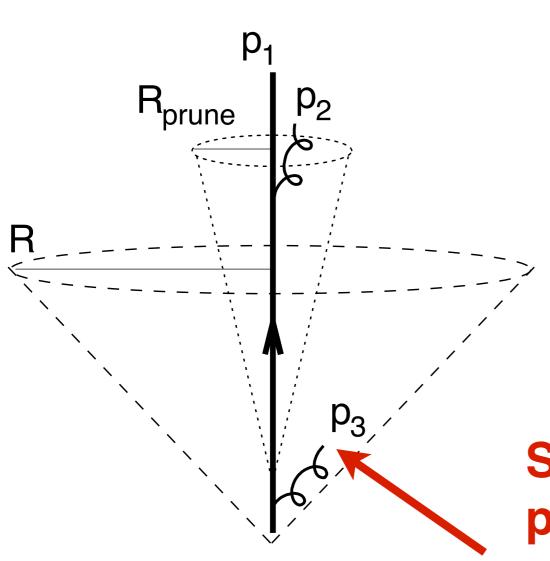

Dynamical choice of R_{prune} means that two prongs are always separated by $> R_{prune}$. So, unlike trimming, *z*_{cut} always applied.

Dynamical choice of R_{prune} means that two prongs are always separated by $> R_{prune}$. So, unlike trimming, *z*_{cut} always applied.

pruning beyond 1st order: consider multiple emissions

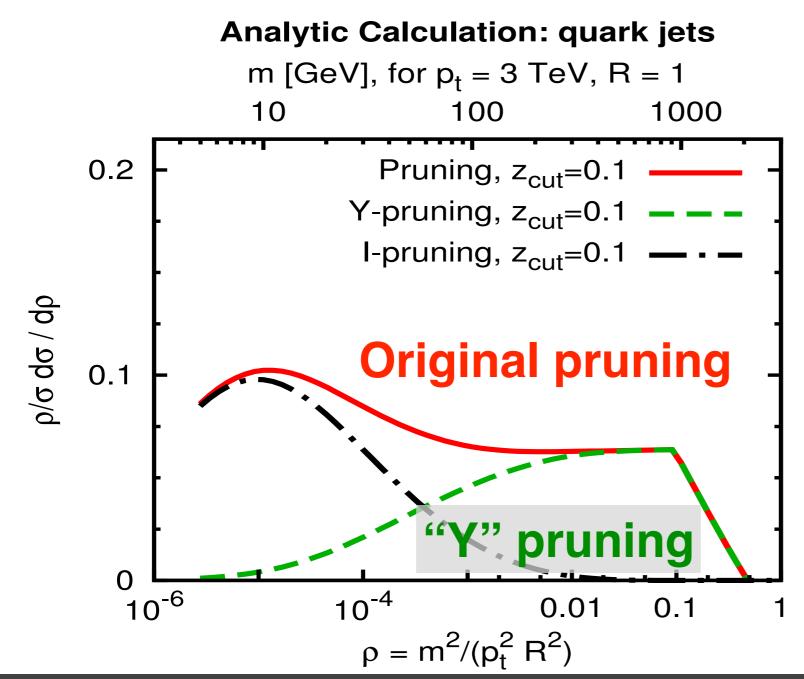

What pruning sometimes does

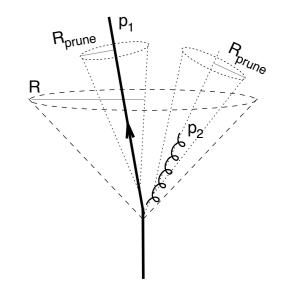

Chooses R_{prune} based on a soft p₃ (dominates total jet mass), and leads to a single narrow subjet whose mass is also dominated by a soft emission (p₂, within R_{prune} of p₁, so not pruned away).

Sets pruning radius, but gets pruned away → "wrong" pruning radius → makes this ~ trimming

A simple fix: "Y" pruning

Require at least one successful merging with $\Delta R > R_{prune}$ and $z > z_{cut}$ — forces 2-pronged ("Y") configurations

"Y" pruning ~ an isolation cut on radiation around the tagged object exploits W/Z/H colour singlet

What logs, what accuracy?

At leading order pruning (= Y-pruning): **no double logs**! $\alpha_s L$, but no $\alpha_s L^2$

Full Pruning's leading logs (LL, in Σ) are:

 $\alpha_s L, \alpha_s^2 L^4, \dots$ I.e. $\alpha_s^n L^{2n}$

we also have NLL

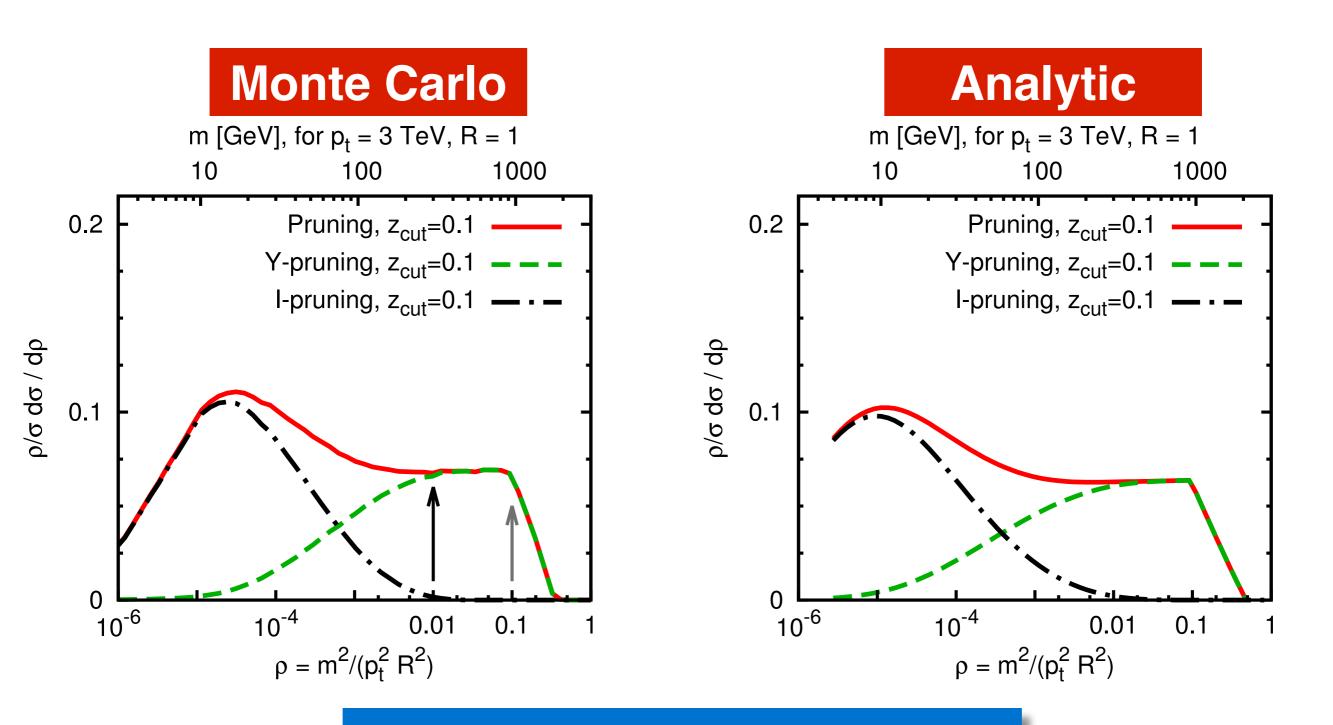

Y-Pruning's leading logs (LL, in Σ) are:

$$\alpha_s L, \alpha_s^2 L^3, \dots$$
 I.e. $\alpha_s^n L^{2n-1}$

we also have NLL

Could we do better? Yes: NLL in In Σ , but involves **non-global logs**, **clustering logs**

quark jets

Non-trivial agreement! (also for dependence on parameters)
